Mike,

I did find TP1...the "1" was partly hidden by a jumper wire...I think J18 ...I do have the X-ray picture(s)...just gotta remember it's reversed. I'll be doing more checking..later...HAPPY NEW YEAR!!! gotta go over to some friends...

Joe and others,

Not being able to see clearly TP1 on the RF Unit is where the service manual's individual PC board "Xray" pictures come into play. The Xray pictures are identical to the actual PC boards and make it easier for you to locate and connect to the correct component or test point.

At any rate the receiver has stopped doing its job, which after 30 years continuous use is to be expected. reason I would like a full board is that the components are too small for me to replace effectively.

29109. VBT-1 Test Set for Aligning TS-830S VBT Oscillator

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-01 15:04:16 UTC
From: wagstw46
Topic: 29109 Message: 29109

Does anyone know what the VBT-1 test set mentioned on Page 38 of the TS-830S service manual is? It appears to be some type of 2 tone AF generator? I just installed full filter pack in my TS-830S gold and want to align the passband windows. I used the method described under the maintenance section of the Survivors Guide to adjust the VBT oscillator and I think I have it close, but would be nice to have access to factory test equipment or to replicate it to perform this alignment.

Thanks and Happy New Year to all
Terry K9TW

Terry,

The signal is RF from an RF signal generator.

Thanks Joe. Ken even says on his web site that he is backed up. Will do that and put 'parts' in the subject line. Happy new year to all here at the forum. I spent all night last night right before new year on my tower changing things around, got a good view of the pyrotechnics. I climbed down at 15 til midnight and only dropped one wrench and 2 washers.

29114. TS-830S reasonable value

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-01 16:17:33 UTC
From: Mike Maiorana
Topic: 29114 Message: 29114

Hello all. I'm thinking about selling my TS-830S and was hoping to get some input as to a reasonable asking price. I've owned it since I got my ticket in 1997 but never use it. I want to clear the bench space. I would rate it (as subjective as this is) a 9.5 out of 10. The only imperfections are two very small rub marks on the top cover, and the cover screws have been used many times so they look, well, used. The serial number is 1081xxxx (silver face). It has two InRad 400Hz cw filters installed. I also have the SP-230, again in near-mint condition. Everything works as it should.

I'm looking for an asking price that reflects its value, without trying to gouge.

Thanks in advance for any help or advice.

In the UK they fetch around £300, not much more, some a little less, but thats the average.

Subject: [TS-520_820_530_830] TS-520 no rcv

Greetings Group,

Rig:TS-520
Problem: limited/no rcv

I have the xmit problem fixed(which was not posted..I actually fixed it...by reading prior posts...yeah..me!!)...but the following is still a problem:

The rcv seems dead. The AF gain will alter the volume as necessary. I can not rcv any signals on any band..with the exception of WWV, which as propagation permits..comes in fine.

The "CAL" signal can only be heard...but very weak on 7MHz and 3.5MHz. The other

bands the "CAL" signal can not be heard at all.

I have looked at the initial start of a long thread..starting with MSG # 28835. I would love to diagnose...repair this myself..but my knowledge..skill..and equipment are minimal. I have a DVM..with RF detector probe,an RF SIG GEN..which

I'm still learning on....and an AF GEN..I'm still learning on..not to mention...an O'SCOPE..which..well is gonna take some time...ANY help, is as usual, appreciated!

Happy New Year.....73's joe wb7uqu

Topic: 29117 Message: 29117

Greetings and Happy New Year..

I know that I can pick-up the "OSC" frequency on my counter from the "HET" connection on the back of a TS-520S..but the 520 has no such provision. Upon looking at schematic of the 520..it appears to be either the "XL" or the "XO" term on the RF board...I have checked both..depends on the band and which terminal..I can get the correct "OSC COIL" freq reading as stated on the manual...some bands no reading..other bands good reading...I can however.. following the procedure in the "book"... adjust the coils to obtain the proper voltage..this is the same 520 with super weak/no receive..even "cal signal" is weak..or not audible...WWV..depending on time of day is strong....ideas??

Hi Joe,

Happy New Year.

You are checking the frequency counter to the wrong places on the RF Unit for the HET OSC signal. Connect your frequency counter to "TP3" on the RF Unit.

Mike,

TNX MIKE... have "OSC" frequencies adjusted to specs...except for 28.0 & 28.5. I understand that the OSC coil for that band affects all three of them The spec says for 28.0MHz it should be 36.895..I get 35.895, for 28.5 I get 36.395...however 29.1 is spot on at 37.995...I picked up a TTY sig on 14.200..confirmed with another radio..changing the band switch had no effect..could still rcv the TTY sig..I am getting really confused...and I did not even drink last night.....

What now?

REPOST

Mike & group

Connected to TP3...got all OSC COILS to correct freq. except the 10meter segment. Adjusting according the manual..you use 28.5MHz and the other two..28.0 & 29.1 should fall inline..well..all I could get on the 28.5 adjustment was 36.l394MHZ..should be 1Meg higher and the 28.0 was the same 1Mhz lower..but 29.1Mhz was spot on. The "CAL" sig is still barely audible on 2 bands..non existent on the rest..I could hear a TTY sig the VFO (dial)said was on 14.200Mhz..but turning the band switch to any of the other bands..it still received the TTY sig. I tuned another rig to 14.200..and noTTY there or any other band covered by the 520..when XX.200 indicated. I don't have a clue on this one! Ideas?

Has someone removed a crystal and replaced it with a CB crystal ?? Very common on 520's to have been either partially or completely changed over to CB and the freeband or whatever they call it frequencies . Might have a look at the crystal frequencies and list them .

Topic: 29117 Message: 29123

I agree, it appears that 28.5Mhz HET OSC crystal 37.395Mhz has been changed to 36.395Mhz for 11 meter operation.

The HET OSC provides the frequency for the first receiver mixer. Here's how the mixing takes place with the current 36.395Mhz crystal in the first receiver mixer. Understand that the 8Mhz signal, 8.895Mhz and 8.395Mhz is within the frequency range of the first mixer output which is the "RIF" signal fed to the IF Unit. I did the conversion "backwards" so you can see how I came up with the correct frequency for the "RIF" signal frequency. This is the easy way to do it. It allows you to tell at a glance whether the HET OSC crystal is factory or a CB Hacker modification! The VFO output frequency varies from 5.500Mhz (bottom of ALL bands) to 5.000Mhz (top of all bands).

1. 36.395 - 8.895 = 27.500Mhz

In example 1 the VFO is tuned to "zero"

2. 36.395 - 8.395 = 28.000Mhz

In example 2 the VFO is tuned to "500".

Both example shown above is how the incoming signal is mixed with the 36.395Mhz HET OSC crystal with the band switch set to 28.5 for the first conversion RIF signal to be between the "required" 8.895Mhz to 8.395Mhz.

The "second" receive mixing occurs on the IF Unit where the VFO signal is mixed with the 8Mhz signal to produce the 3.395Mhz "IF" signal that is applied to the crystal filter.

Lets say the VFO is tuned to "zero". This results in a VFO output frequency of "5.500Mhz". This also results in an "8.895Mhz" "RIF" signal that is applied to the IF Unit. Therefore, the second receive mixer produces the following:

8.895 - 5.500 = 3.395Mhz

As I said the 520's "IF" frequency of 3.395Mhz is then applied to the crystal filter and processed and fed to the GENERATOR UNIT where it is applied to the balanced detector (ring detector) where the audio is recovered. The audio is then applied to the audio amplifier on the AF Unit then fed to the speaker.

You will have to replace the 28.5Mhz HET OSC crystal with a 37.395Mhz crystal to put 28.5Mhz band switch setting back to its original factory frequency.

You should also check the final amplifier PI Network components and connection to ensure there have not been any modifications made. Any modifications/wiring changes must be removed and the final amplifier PI Network wired back to factory wiring.

I hope I have not confused any of you by the example I provided. It is important to understand how the receive and transmit signals are processed and what specific frequency will be at certain positions along the signal path. This will help you troubleshoot such

problems as this.

Mike & Charlie,

I never gave that a thought...but guess what? You're right....sure enough two XTAL's X5 & X6 on the OSC board have been changed. I should have been tipped off by the sloppy resolder job on the grounding foil/plate/screws...not to mention the "silver xtal cans" vs the grey plastic coated ones...at least one of the "new" cans has "KENWOOD" printed on it....I do have some of the proper XTALS on a junk 520 I can use for repair...then I'll check the final cage area...then go back to the receive problem...this is getting deep...but a VERY good learning lesson! TNX!!

Has someone removed a crystal and replaced it with a CB crystal ?? Very common on 520's to have been either partially or completely changed over to CB and the freeband or whatever they call it frequencies . Might have a look at the crystal frequencies and list them .

Morning Joe,

The individual band ANT COIL Unit coils are wired in "series". Adjusting of each coil is performed in a specific order.

Since we now know that the 520 has been modified for 11 meter operation, the ANT COIL Unit alignment is more than likely "out of alignment" which can easily affect receive. We also do not know what other changes/modifications have been done. Therefore a thorough visual inspection of the RF Unit and ANT, MIXER, and DRIVER COIL Unit boards should be done using the 520 service manual's RF UNIT schematic as your guide.

You said the soldering of the board was poor. I recommend checking the solder connections to be sure they are done properly. A fault ground due to poor soldering can affect how the coils in the ANT, MIXER, and DRIVER are working. A poor solder connection may show a good "DC" indication but will fail or present a high resistance to RF.

In addition, the ANT, MIXER, and DRIVER coils must be adjusted in a specific order as outlined on page 40 of the 520 service manual. Therefore, once you replace the 10 meter HET OSC CB crystals with the correct HET OSC crystals, I recommend you perform an alignment starting on page 39 of the 520 service manual.

Morning Joe/Mike,
I have been following the case with interest. I note your comments (Joe) that the soldering has been poorly done and (2) Mike that the front end may be out of alignment.

I ask: Was the set known to be working in the citizens band? I offer the possibility that an unknown person began to modify your set for CB operation, BUT FAILED TO COMPLETE THE JOB. "Modding" demands a certain ability - and the poor solder joints observed may indicate that was lacking.

Good success & 73s

Les,

The resoldering job...I should say was not...say cold solder...just a bit more glob-like and bright..versus the more professional "factory look" which also has dulled with time. Also, I could hear signals...but could not cross reference them with another receiver..the 520 seemed to be "stuck" on/around the 11meter band...as changing the band switch had no effect. I do have to commend...to a point..the person who took this rig partly apart..as you might know...its a real pain to get those boards out...and get back together...but I guess I'll deal with one at a time...who know...a miracle MAY occur..

Hi Mike,

I would check the various classified and auction sites and see what they are asking/getting. On ebay, if you are registered, you can check "completed items" in the left menu and get a summary of completed auctions for your items and also a summary of those offered for sale which were not sold (did not reach reserve bid). In addition to ebay I would check qth.com and qrz.com. There may be others of which I am ignorant.

Mike--I think you are right as they are putting input from this VBT-1 set into IF jack on back of rig. If it was audio they would be going into the mike connector on the front. The waveform they show looks like 2 tone test. I see that Elecraft has a 2-tone generator kit that I might consider building. Richard Measures method described in the Survivors Guide uses the 25 khz calibrator and I think I got it pretty close doing it his way. Only thing that now seems a little off is the IF shift. It is not equal in both directions of the pot. I am looking at the effects of the VBT pot and the IF shift pot on the passband using a audio spectrum analyzer software I downloaded called Spectogram. You take audio from headphone jack thru a homebrew padder and connect to your laptop thru the sound card line input. Kind of fun to see this. Thanks for responding. I suspect not too many hams purchased the VBT-1 test set or if it was even available for sale from Kenwood? Thanks Mike for responding. Terry K9TW

Mike,

The 830S including the Inrad CW filters and in collectors item condition should go between 450 - 500 USS. The SP-230 in perfect condition around 100 - 125 USS. When you search all the second hands sites like ebay, qrz.com etc. you will see these prices.

Good luck with the sell. 73's Ger PE1CZG

Topic: 29109 Message: 29134

Any signal injected to or taken from the IF Unit as described in the service manual VBT adjustment is "RF" not "AF".

The only "AF" signal(s) in the IF Unit are the result of "audio recovery" by the "balanced detector" on the IF Unit. The "recovered audio" signal is then fed "from" the IF Unit "to" the AF Unit to be applied to the audio amplifier and heard in the speaker.

Topic: 29117 Message: 29135

You said changing the VFO and band switch does not affect the "ghost" or "phantom" signal. If I am wrong then please correct me.

This could be caused by improperly adjusted series and parallel "traps" (L11/C51 and L5/C34). L3 on the ANT COIL UNIT is another trap that if improperly adjusted could lead to improper operation. If removing the antenna causes the "ghost" or "phantom" signals to disappear then the signals are coming into the 520 from the antenna. That's why I said to perform a thorough alignment after you are sure any wiring changes and mods have been removed and the 520 is back to it's factory state.

While it's possible a previous owner, a CB hacker, or a CB hacker "wanna-be" tried to modify the 520 and didn't finish, it is obvious there were other wiring changes that have been done. This is why I said to do a thorough visual inspection of the 520 using the 520 schematic as a guide. You have no idea what has been done to this 520 by a previous owner or CB hacker. These types of problems unfortunately take a lot of time to do. One needs to think "outside the box" when troubleshooting these types of problems. As I say quite often, don't assume anything, verify it to be sure.

HNY 2011!
I still cannot get the lumens or candlepower on the panel bulb with a 12v bulb! I see video on YouTube with a TS820s, and the VFO lamp bulb is very bright! Mine is a sort of dim version of same...the smeter is b right and cheery.

Guess the grain of rice bulbs from the STates will be needed.

thanks in advance for tips...

Morning Joe/Mike,
I have been following the case with interest. I note your comments (Joe) that the soldering has been poorly done and (2) Mike that the front end may be out of alignment.

I ask: Was the set known to be working in the citizens band? I offer the possibility that an unknown person began to modify your set for CB operation, BUT FAILED TO COMPLETE THE JOB. "Modding" demands a certain ability - and the poor solder joints observed may indicate that was lacking.

Good success & 73s

Morning Joe,

The individual band ANT COIL Unit coils are wired in "series". Adjusting of each coil is performed in a specific order.

Since we now know that the 520 has been modified for 11 meter operation, the ANT COIL Unit alignment is more than likely "out of alignment" which can easily affect receive. We also do not know what other changes/modifications have been done. Therefore a thorough visual inspection of the RF Unit and ANT, MIXER, and DRIVER COIL Unit

boards should be done using the 520 service manual's RF UNIT schematic as your guide.

You said the soldering of the board was poor. I recommend checking the solder connections to be sure they are done properly. A fault ground due to poor soldering can affect how the coils in the ANT, MIXER, and DRIVER are working. A poor solder connection may show a good "DC" indication but will fail or present a high resistance to RF.

In addition, the ANT, MIXER, and DRIVER coils must be adjusted in a specific order as outlined on page 40 of the 520 service manual. Therefore, once you replace the 10 meter HET OSC CB crystals with the correct HET OSC crystals, I recommend you perform an alignment starting on page 39 of the 520 service manual.

JOe,

I have been following along with the problems and post with your TS-520. I really don't have anything to add or suggest but did notice something in your posts that I am curious about; not sure it has any bearing on your situation or not. A few post back you mentioned that there were two crystals that appeared to have been changed....X5 & X6 on the OSC board. I have a TS-520 that was modified for 11m and as far as I know there was only (1) crystal that was changed. Perhaps some of the other guys in the group might know more about the modification, but why (2) crystals? Is changing (2) required for the modification or did something go bad and get changed? Perhaps verification of the freq. of the 2nd crystal is inorder? Also, as I think you already know, inorder to change the crystal they would have had to disassembled the coil pack. It appears that the disassembly/ reassembly process is very tidious. I would verify that the coil pack has been reassembled propery. I would bet that even the length and position of the spacers would affect the operation of the OSC and coils. Just some thoughts on your situation.

29140. Re: TS 520 "OSC" freq's

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-03 15:37:16 UTC
From: w5rkl
Topic: 29117 Message: 29140

Joe, Les, and others,

The original CB band starts at 26.965 for channel "1" and ends at 27.405 for channel "40". You can see the individual change frequencies at the following website.

http://www.firestik.com/Tech_Docs/CBFREQ.htm

You will notice that each channel has a 10Khz space between each channel but not all channels have the same 10Khz spacing, some are spaced "15Khz" apart such as between channels 3 and 4, channels 11 and 12, and so on.

Ham gear, such as the TS-520, that has been modified to operate on 11 meters typically changes the 28.0 and 28.5 band switch HET OSC crystals. This provides the CB operator a range of frequencies from 27.0Mhz to 28.0Mhz, a 1Mhz range of frequencies! When modified, the TS-520 VFO is NOT channalized but rather "variable between any frequency from 27.0Mhz to 28.0Mhz is available to the operator!

I won't repeat what I said in an earlier response, how the mixing process occurs and how each mixer's output produces the desired signal at certain points along the signal path and how the HET OSC crystal affects both transmit and receive mising.

When the modifications are performed, the appropriate HET OSC coil and DRIVER coils must be readjusted. This will affect the 520's 10 meter receive and transmit when the CB Hacker crystals are replaced with the original ham band 10 meter HET OSC crystals! The CBer, in most cases, not all, is not interested in the other bands. He/she is only interested in talking to his buddies on 27Mhz to 28Mhz.

It's not a simple matter of only replacing the HET OSC crystals then starting transmitting on 10 meters again! I have said a number of times that a thorough inspection, after replacing the CB HET OSC crystals with the proper ham band crystals, should be done. I say this because you do NOT know what has been done to the 520 other than changing the HET OSC crystals! You also do not know the skill of the person doing the modification either! Most CB mods to the 520 only adjust the HET OSC Coil and driver coils for the bands they modified. When that happens it upsets the entire receiver and driver Coil Pack which affects ALL bands! This is why I say an alignment should be done, to ensure the 520 is operating at peak performance after installing the original HET OSC crystals! As I always say, never assume anything, always check and make adjustment as needed to be sure!

Mike & group,

Well..here's the news..replaced the "hack" xtals with the proper ones...thank GOD I had an un-rap/rap tool. Put it back together...and...prayed..hit the power switch...and power...but no audio...I can however I can turn on the JJY/WWV switch and rcv WWV ...adjusting the AF gain here works fine....just nothing...when JJY/WWV switch not on.. DEAD.I think for now..I'll put it up...and take a breather.. I can not detect any overt changes except for what was stated in prior messages. This is currently beyond my skill/equipment level...so unless someone out there...has any ideas..it's going back to the closet for awhile.

Subject: [TS-520_820_530_830] Re: TS 520 "OSC" freq's

Joe, Les, and others,

The original CB band starts at 26.965 for channel "1" and ends at 27.405 for channel "40". You can see the individual change frequencies at the following website.

http://www.firestik.com/Tech_Docs/CBFREQ.htm

You will notice that each channel has a 10Khz space between each channel but not all channels have the same 10Khz spacing, some are spaced "15Khz" apart such as between channels 3 and 4, channels 11 and 12, and so on.

Ham gear, such as the TS-520, that has been modified to operate on 11 meters typically changes the 28.0 and 28.5 band switch HET OSC crystals. This provides the CB operator a range of frequencies from 27.0Mhz to 28.0Mhz, a 1Mhz range of frequencies! When modified, the TS-520 VFO is NOT channalized but rather "variable between any frequency from 27.0Mhz to 28.0Mhz is available to the operator!

I won't repeat what I said in an earlier response, how the mixing process occurs and how each mixer's output produces the desired signal at certain points along the signal path and how the HET OSC crystal affects both transmit and receive mising.

When the modifications are performed, the appropriate HET OSC coil and DRIVER coils must be readjusted. This will affect the 520's 10 meter receive and transmit when the CB Hacker crystals are replaced with the original ham band 10

meter HET OSC crystals! The CBer, in most cases, not all, is not interested in the other bands. He/she is only interested in talking to his buddies on 27Mhz to 28Mhz.

It's not a simple matter of only replacing the HET OSC crystals then starting transmitting on 10 meters again! I have said a number of times that a thorough inspection, after replacing the CB HET OSC crystals with the proper ham band crystals, should be done. I say this because you do NOT know what has been done to the 520 other than changing the HET OSC crystals! You also do not know the skill of the person doing the modification either! Most CB mods to the 520 only adjust the HET OSC Coil and driver coils for the bands they modified. When that happens it upsets the entire receiver and driver Coil Pack which affects ALL bands! This is why I say an alignment should be done, to ensure the 520 is operating at peak performance after installing the original HET OSC crystals! As I always say, never assume anything, always check and make adjustment as needed to be sure!

From: Greg Anders
Topic: 29142 Message: 29143

There are several tricks to reduce drift, however in the 530 and 830 the VFO main capacitor was a problem itself. Somewhere in the production run between the 820S and the newever 530/830 Kenwood changed vendors. The earlier 820 radios had a capacitor with phenolic spacers between the rotor/stator plates. They went to a different capacitor with "plastic". The plastic reacts differently with temperature. So, someone here on the list may have some good hints, however I found only one solution in the three 830s I owned at various times over the past 20 years. A "huff-n-puff" VFO stabilizer kit. Google it and you can learn all about them and find folks still selling the kits.

I would start by loosening and re-tightening all the screws that hold
the boards down.
Next I would make sure the 9 volt and the 3.6 volt circuits are adjusted
right on the money on the AVR board. (the screws on the AVR board are
very important to be tight)
Loose grounds (screws) on the boards are the biggest cause of drifting
from what I have found.

Dan,

X5 & X6 on the OSC board were both changed during the "MOD." I removed the board...that was fun..and the "cans" had their freqs imprinted on the outside...both were 1MHz lower that what schematic indicated they should be. All other xtals are as stated in the schematic. I am not as yet very good at diagnosis/troubleshooting/repair...somethings.. for now.. are beyond my skill/equipment level. There is some other stuff going on...but, I think for now..it's going to go back in the closet..maybe when I take it out...it will cooperate! hi hi

JOe,

I have been following along with the problems and post with your TS-520. I really don't have anything to add or suggest but did notice something in your posts that I am curious about; not sure it has any bearing on your situation or not. A few post back you mentioned that there were two crystals that appeared to have been changed....X5 & X6 on the OSC board. I have a TS-520 that was modified for 11m and as far as I know there was only (1) crystal that was changed. Perhaps some of the other guys in the group might know more about the modification, but why (2) crystals? Is changing (2) required for the modification or did something go bad and get changed? Perhaps verification of the freq. of the 2nd crystal is inorder? Also, as I think you already know, inorder to change the crystal they would have had to disassembled the coil pack. It appears that the disassembly/ reassembly process is very tidious. I would verify that the coil pack has been reassembled propery. I would bet that even the length and position of the spacers would affect the operation of the OSC and coils. Just some thoughts on your situation.

Joe,
It sounds like Q5 on the RF board is bad since WWV goes through Q9,
but BEWARE, I have had a 520 thru here that was backwards from the
Schematic. Q5 was for WWV and Q9 was for normal operation.
You need to check them both. I'll bet one is Bad causing your no
reception other then WWV

Hi Joe,

Good luck with getting your 520 back in the bands.

Please be sure to document your work, even a few
photos uploaded to the Photo section of the group
can help others with similar repairs.

Note that there was a Kenwood documented modification
to the transverter connection per the TV-502 manual pg 9
section 3.6 HF/VHF changover.

Topic: 29150 Message: 29150

Hi OM/YL's;

I'm happy to join the group after just getting a TS-820. I'm a 2 year ham veteran (HI HI). The rig looks good, cost $150, and worked FB to my surprise - since when I bought her the digital display was dead and little info was known about the rig in general. Well, I got it home and even the digital dial worked (though I have to clean it as sometimes it flakes out and dies) and I made many QSO's on 40,20,15, and 10m cw and some on SSB where I got great audio reports. She sounds so good and has great ears! I finally know what that means!

Then, this morning my heart sank as the FB CW sigs started chirping like a sick little chick! This is intermittent - mostly the rig sounds good, but off and on chirps.

The chirp seems to happen:

1. irrespective of the rig being warm or just turned on after a long or short rest
2. on all the bands CW and also when I check SSB (it is wavering too)
3. I tried flipping all switches at random and nothing helps
4. I noticed that "tuning around" seemed to correlate with it getting better, but can't be sure (could be coincidence e.g. post hoc ergo propter hoc)
5. but, 4 above made me start to play with the main tuning dial and I noticed the sigs waver a bit when I touch the dial or push in on the center of it toward the rig.

I know this is a sketchy outline and that chirp might well be a tough nut to crack, but any ideas?

I am a real neophyte on radios (built a couple of kits) so I might be sending it off, but if it is something like a VFO cleaning and lube maybe I could try it out.....

VRY 73, DE Jacob K4JQV

and thanks!

Joe,

After installing the new crystals did you try tuning as Mike had suggested?

Gordon,

Nice to "see" ya..hope all is still well....I'm taking a break from that rig
for a few..but I'll save this post..and check it out and let you and the group
know what else I find out. This was not a real sloppy "hack" job. Who ever did
the OSC board had the proper un-wrap/wrap tool..you had to look real close to
see just a bit of copper under the nickel plating that was scraped off the
wires. The rig has multiple problems..as you can tell...and right now my skill
level is not up to some of the problems(s) I may encounter...but with you, mike,
and the rest of the group I've already come a long way... well enough for now

73's joe wb7uqu

Joe,
It sounds like Q5 on the RF board is bad since WWV goes through Q9,
but BEWARE, I have had a 520 thru here that was backwards from the
Schematic. Q5 was for WWV and Q9 was for normal operation.
You need to check them both. I'll bet one is Bad causing your no
reception other then WWV

Dan,

Well...got the board done and back in...turned it on..got lights..but now no audio..except when JJY/WWV switch is activated...Gordon, n6wk, most likely Q-5 or Q-9 if there was a "wiring" change. I'm going to take a break from it..and chill out for a day or two

Joe,

After installing the new crystals did you try tuning as Mike had suggested?

Hi Guys. Back in 1990 when I was first licensed, I had a TS-520 that had been "converted" for 11M use. Not only had the 10M crystals been changed, but CW mode had been converted to AM (still worked on CW with mic removed). I managed to change the crystals to the correct ones and performed the alignment in the manual. I never did figure out how to reverse the AM mod though.

I don't have the radio anymore, but it worked pretty well on SSB. A year or three ago I came across an AM mod for the TS-520. It was a fairly involved mod. It is too bad that these radios are modified for 11M use, sometimes by those not qualified to do so.

Hi Jacob ...you did quite a good report of symptoms.!!...all I can say is thaT i HAVE A 530 (VERY SIMILAR TO 820) AND AT THE EDGES OF THE vfo tuning range THE AUDIO GOES SILLY which I assume to be a dirt problem 'cos turning the dial back and forth over the dodgy area clears it .
Cheers Pete

Subject: [TS-520_820_530_830] New member, new rig, small problem

Hi OM/YL's;

I'm happy to join the group after just getting a TS-820. I'm a 2 year ham veteran (HI HI). The rig looks good, cost $150, and worked FB to my surprise - since when I bought her the digital display was dead and little info was known about the rig in general. Well, I got it home and even the digital dial worked (though I have to clean it as sometimes it flakes out and dies) and I made many QSO's on 40,20,15, and 10m cw and some on SSB where I got great audio reports. She sounds so good and has great ears! I finally know what that means!

Then, this morning my heart sank as the FB CW sigs started chirping like a sick little chick! This is intermittent - mostly the rig sounds good, but off and on chirps.

The chirp seems to happen:

1. irrespective of the rig being warm or just turned on after a long or short rest
2. on all the bands CW and also when I check SSB (it is wavering too)
3. I tried flipping all switches at random and nothing helps
4. I noticed that "tuning around" seemed to correlate with it getting better, but can't be sure (could be coincidence e.g. post hoc ergo propter hoc)
5. but, 4 above made me start to play with the main tuning dial and I noticed the sigs waver a bit when I touch the dial or push in on the center of it toward the rig.

I know this is a sketchy outline and that chirp might well be a tough nut to crack, but any ideas?

I am a real neophyte on radios (built a couple of kits) so I might be sending it off, but if it is something like a VFO cleaning and lube maybe I could try it out.....

VRY 73, DE Jacob K4JQV

and thanks!

Sounds like you need to clean the main tuning capacitor with some tuner cleaner. Make sure you clean the end with the clip/ contact on it. I used a non-residue contact cleaner on the fins and deoxit on the clip when I did mine. After 20-30 years of service the contact may have developed a tiny bit of corrosion and needs to be cleaned.

From: w5rkl
Topic: 29117 Message: 29158

The reason the 520's receiver appears dead, nothing heard in the speaker other than thermal and mixer noise "hiss" when tuning the normal ham bands is because there is no signal to process! The JJY/WWV receive works but ham bands do not. That, in itself, eliminates a lot of circuits as the source of the problem. The problem lies on the RF Unit, either in the RF amplifier Q5 or the COIL Unit. Having read the response numerous times, it is my belief the problem is Q5.

That is my thought also Mike. I would definitely start by checking Q5

You have a dirty VFO tuning capacitor. After 30+ years the capacitors need a clean-out. All you need to do is open up the VFO spray de-oxit on the capacitor rotor ground clips mounted on the end frame and clipped into the rotor. Work the VFO numerous times thru the complete frequency range and the de-oxit will clean and lubricat the clips and rotor so you have a consistently good ground connection.

FYI,

Greg

Subject: [TS-520_820_530_830] New member, new rig, small problem

Hi OM/YL's;

I'm happy to join the group after just getting a TS-820. I'm a 2 year ham veteran (HI HI). The rig looks good, cost $150, and worked FB to my surprise - since when I bought her the digital display was dead and little info was known about the rig in general. Well, I got it home and even the digital dial worked (though I have to clean it as sometimes it flakes out and dies) and I made many QSO's on 40,20,15, and 10m cw and some on SSB where I got great audio reports. She sounds so good and has great ears! I finally know what that means!

Then, this morning my heart sank as the FB CW sigs started chirping like a sick little chick! This is intermittent - mostly the rig sounds good, but off and on chirps.

The chirp seems to happen:

1. irrespective of the rig being warm or just turned on after a long or short rest
2. on all the bands CW and also when I check SSB (it is wavering too)
3. I tried flipping all switches at random and nothing helps
4. I noticed that "tuning around" seemed to correlate with it getting better, but can't be sure (could be coincidence e.g. post hoc ergo propter hoc)
5. but, 4 above made me start to play with the main tuning dial and I noticed the sigs waver a bit when I touch the dial or push in on the center of it toward the rig.

I know this is a sketchy outline and that chirp might well be a tough nut to crack, but any ideas?

I am a real neophyte on radios (built a couple of kits) so I might be sending it off, but if it is something like a VFO cleaning and lube maybe I could try it out.....

VRY 73, DE Jacob K4JQV

and thanks!

Dan,

Something about 3 months ago told me ..."YOU NEED THIS!" I usually don't
listen to the voices in my head anymore...but this would not go away..hihi.
There are several companies/dealers..but the cheapest...if you can call $49.95
(USD) cheap for a metal stick to twist wires..well...this is a quality tool...
Made to both wrap and unwrap 22-24 awg wires...no insulation can be on the
length being twisted. It is made by JONARD...Model # WDUD-2224... I got it
through Circuit Specialists, Inc....www.web-tronics.com

[Non-text portions of this message have been removed]

29165. TRADE ??? TS-520 CW Filter wanted, Have VFO-820 or SP-520 to trade.

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-04 20:30:03 UTC
From: Ken
Topic: 29165 Message: 29165

I am looking for a CW Filter for my TS-520 and have a working, calibrated, good looking VFO-820 with cable or an SP-520 in same condition to trade.

My contact info on QRZ.com is correct.

73,

Ken - KB7H

29166. Re: [TS-520_820_530_830] Re: TS 520 "OSC" freq's

Dan,

clarification..."no insulation on the ends being twisted"

From: Joseph Stiles <stilesjoseph@...>
To: TS-520_820_530_830@yahoogroups.com
Sent: Tue, January 4, 2011 12:06:55 PM
Subject: Re: [TS-520_820_530_830] Re: TS 520 "OSC" freq's

Dan,

Something about 3 months ago told me ..."YOU NEED THIS!" I usually don't
listen to the voices in my head anymore...but this would not go away..hihi.
There are several companies/dealers..but the cheapest...if you can call $49.95
(USD) cheap for a metal stick to twist wires..well...this is a quality tool...
Made to both wrap and unwrap 22-24 awg wires...no insulation can be on the
length being twisted. It is made by JONARD...Model # WDUD-2224... I got it
through Circuit Specialists, Inc....www.web-tronics.com

Joe,

Where did you get the wrap/ un-wrap tool? Are they still available?

Joe,

tnx fer kind offer...hang on to it for right now..I have 2 taken from a non-working unit...don't know right now is they are ok...if not...I have a couple to new NTE222's in the "bin."

73's joe wb7uqu

Joe: Give me a call at 425.747.5349 Bellevue. I have a good 3SK35 that you can try in your 520's RF board at Q-5.

Joe: As Q5 is a plug in unit the NTE222 should be easy to install and also should work fine.

My TS520 started acting like that a few years ago when tuning from one end of band to the other. When I want to tune out of my comfort range (3.5-3.565 kHz) I find various dead spots that can be recovered by rapidly tuning the knob back and forth a few times.
I have not taken the radio all apart to get at the VFO parts because I only use this rig on 80M CW !

Sounds like you need to clean the main tuning capacitor with some tuner cleaner. Make sure you clean the end with the clip/ contact on it. I used a non-residue contact cleaner on the fins and deoxit on the clip when I did mine. After 20-30 years of service the contact may have developed a tiny bit of corrosion and needs to be cleaned. Thanks to all of you! I have the DeOXIT from Radio Shack and I will soon try to clean that VFO VC.

Best;
Jacob

> You have a dirty VFO tuning capacitor. After 30+ years the capacitors need a clean-out. All you need to do is open up the VFO spray de-oxit on the capacitor rotor ground clips mounted on the end frame and clipped into the rotor. Work the VFO numerous times thru the complete frequency range and the de-oxit will clean and lubricat the clips and rotor so you have a consistently good ground connection.

Joe,

Thanks for the info. I'll go check out the link and see what it looks like. I am in no hurry so I'll look at the next hamfest; maybe I'll get lucky. I certainly did not expect them to be that expensive. I'm sure sooner or later I will find one more in line with my budget.

Some MOSFET transistors have a safety shorting wire wrapped around the leads. This helps prevent damage to the transistor from static discharge by simply handling the transistor with your fingers.

If the transistor comes with a safety shorting wire do not remove the shorting wire until the transistor is installed. Once the transistor is installed then remove the safety shorting wire. Don't forget to remove the safety shorting wire if the transistor comes with one. I forgot to remove the shorting wire when I built an HW-7 from a kit. The symptom was a "dead" receiver. When I removed the safety shorting wire the receive came to life. I'm not sure whether the NTE222 or a new 3SK35 comes with a safety shorting wire wrapped around the leads or not. Check to be sure.

None of the NTE222's i have purchased have ever had a shorting wire.

Mike,

Tnx agn for the handy info...this NTE222 is still in the plastic (clear) and I can see that it does not have the shorting wire. Must remember to follow static precautions. I do really hope that it is Q-5..kinda of a "plug-n-play." If I have to get at Q-9 or any others for that matter..on that RF board...I might scream.

None of the NTE222's i have purchased have ever had a shorting wire.

No problem Joe. Older MOSFETs did have safety wires wrapped around their leads. However, more than likely today's MOSFET have diodes built in to the transistor that do the same thing the safety wire did in the old days of MOSFETs. I still remember to this day the MOSFET transistor in the HW-7. I saw the wire, left it on the transistor like the instructions said but I failed to remove it before powering up the HW7. I was ready to do some QRP work but what, the receiver's dead. I went through the instructions and when I came across the instruction about the wire I looked and sure enough it was still wrapped around the leads. I pulled it off and the receive came to life, didn't harm anything, just a bone head mistake by me!

Let us know what happens after replacing the receiver's RF amplifier. Make sure the schematic diagram of the RF Unit is the one for the RF Unit in you 520. The board has a number, X44-1080-0). Check your RF Unit board number with the number on your schematic, they should be the same. Changes made could cause the 'suffix' number to change from zero to 1 or possibly 01 so pay attention that that. You board number and the schematic board number should be the same.

Nigel,

What mode (TUNE, CW, USB, or LSB) are you experiencing loss of RF output? If you are transmitting in USB or LSB mode then you will need a microphone connected to the 530's microphone socket, press the PTT button, and adjust the MIC gain control while speaking into the microphone to achieve any RF output. This is assuming the 530 is properly tuned up for the frequency you intent to use and the 530 is connected to either a dummy load or an antenna cut for or resonant to the intended frequency.

If you do not have the 530 operator's manual then go to Gordon's website

www.n6wk.com/kenwood/

and download the manual free. Take some time and read the manual thoroughly before attempting to operate the 530.

Nigel,

Also check the rear panel's "SG" switch, it must be in the "ON" position for normal operation. Quite often people handling or moving the transceiver can accidently move the SG switch to the OFF position which will result in loss of power output.

The front panel "HEATER" switch must also be turned ON otherwise the driver and final tube filaments will not heat up which can result in loss of power output in all modes.

Topic: 29180 Message: 29180

Good morning, I'm sitting here with my TS-520, and as much as I love it, I am hard-pressed to appreciate the VFO, I was curious if there's a good place in the radio to connect a frequency counter (I am aware that I most likely won't see the actual frequency), but I'm looking for a number that I can reference, I commonly run at the edge of 75m, and would prefer not to transmit out of band..

I also feel kind of silly tossing my call a few kc's off of frequency, and would like to be dead on when I key up... I've shelved my FT-857D in favor of this rig due to the better receive qualities in comparison, but I long for a digital reference to my analog frequency adjustment...

Any assistance, input, crude commentary, would be greatly appreciated.

Bill,
I have had my TS-520 for about 25 years. I bought it second hand and it came with A Spectronics DG-5 that tracked real well just like just like a built in frequency display. This was hit by lightning and I never saw another one. I then purchased an external frequency display from Palomar Engineers. They made these units specific for many of the old Kenwood and Yaesu hybrids that did not have displays. This was about 10 years ago and I am not sure if they are still available. I am still using it and it works real well. Kenwood also made a DG-5 that was a nice display specific for the 520 and 520s. That would be your best bet. You sometimes see them on Ebay. Make sure it comes with the connection module and wring information.

Good luck, 73s
Mike N8YOK

Hi Bill,

A frequency counter connected to the VFO will only display the VFO frequency which is between 5.500Mhz (zero on the VFO dial) to 5.000Mhz (500 on the VFO dial). Using this method you would have to mathematically calculate your actual operating frequency from the frequency counter display (3.39x.y + VFO = 8Mhz TIF frequency. Then subtract the 8Mhz TIF signal from the HET OSC crystal frequency to achieve the actual transmit frequency). For example if the frequency counter displays 5.425, the actual operating frequency will be:

Approximate transmit and receive frequency (40 meters CW)

3.395.0 + 5.425 = 8.820Mhz (TIF frequency fed to the RF Unit transmit mixer)

15.895 - 8.820 = 7.075Mhz (actual operating frequency)

3.395.0Mhz signal is the CAR Unit crystal frequency selected by the "Mode" switch.

5.425Mhz is the output frequency of the VFO set to x.070 on the dial.

15.895Mhz is the 40 meter HET OSC crystal frequency.

A better solution is to use the Kenwood DG-5 which will display your actual transmit and receive frequency. Depending on the model of 520 you have will determine whether the DG-5 is "plug and play" with your 520. The first 520 did not have HET, VFO, and CAR sockets plus a 13.6VDC power socket on the rear panel connect the DG-5 to the 520 and to power the DG-5. If your 520 is the first 520 then you will have to modify (add connections to the VFO, HET OSC, and CAR Unit outputs) for those signals and voltage to appear at the rear panel sockets.

Good Afternoon Group:

It has taken several years, to get the mothballed HF station back on the air after moving into our condo, especially with the condo Gestapo and all of the restrictions that implies.

Made my first contact this past weekend on 40 and felt like a novice again.

Which leads me to ask... are there any mods for the TS-820S that will result in upgraded performance or convenience of operation?.

In closing, I would like to extend my thanks and appreciation to the many members of the invaluable group who give of their time and talents so freely.

Remember, that for every Ham that may ask a question, there are countless lurking in the shadows and learning through the camaraderie that this Group imparts.

tnx es 73, 76

The YK-88SN is the 1.8Khz sideband filter verses the 2.1Khz YK-88S sideband filter. The filters themselves are the same except for the bandwidth and that the YK-88SN-1 is mounted to a PC board. Check the 530's service and/or operator's manual on installing the narrow sideband filter for any changes you need to make "BEFORE" you install the narrow sideband filter.

There should be more than enough drive from the driver tube to produce a full scale ALC indication during tune up in TUNE mode with the CAR control set to no higher than 11 or 12 o'clock and adjusting the DRIVE control. If the ALC indication peaks then drops off without touching anything then the driver tube should be replaced. Don't replace tubes unless you are sure they are the source of low power output.

Check the final tube's HV at the Rectifier Unit's "800" terminal first. It should be approximately 925VDC in standby (receive) and less in transmit depending on the final amplifier's power output. A weak HV filter capacitor could lead to lower final tube plate voltage which can affect the power output. I'm not saying the HV filter capacitors in your 530 are bad, just another possible cause for low power output. A bad HV filter capcitor can result in the HV becoming half it it normal voltage level.

Naturally cleaning the band switch and mode switch wafers can help as well.

I would to know what I should do to get the best performance from this rig on cw recieve. What filters should I get to enhance the performance
I like to work cw and get good signal reports but I would like to have a more selective and quiet recieve. I have considered buying another rig for cw but hate to spend the money if it isn,t necessary.

Thanks
Steve

Subject: [TS-520_820_530_830] TS-520 frequency counter query...

Good morning, I'm sitting here with my TS-520, and as much as I love it, I am hard-pressed to appreciate the VFO, I was curious if there's a good place in the radio to connect a frequency counter (I am aware that I most likely won't see the actual frequency), but I'm looking for a number that I can reference, I commonly run at the edge of 75m, and would prefer not to transmit out of band..

I also feel kind of silly tossing my call a few kc's off of frequency, and would like to be dead on when I key up... I've shelved my FT-857D in favor of this rig due to the better receive qualities in comparison, but I long for a digital reference to my analog frequency adjustment...

Any assistance, input, crude commentary, would be greatly appreciated.

73, KE7SZC, Bill.

It is the adjacent stations that are causing the problem, I don't have any filter in it.

The TS-830S has 2 factory 2.7Khz sideband filters installed. One is an 8Mhz IF filter and the other is a 455Khz filter. The narrow sideband and CW narrow or wide filters are "optional". You can purchase additional filters for your 830 from INRAD at the following link:

http://www.inrad.net/home.php?cat=55

If you change filters, such as changing to a more narrow sideband filter or adding CW filters, you should change both 8Mhz and 455Khz filters. The same goes for installing CW filters, install both, not just one.

Adjacent interference can be reduced and/or eliminated by adding better filters. If adding filters is not an option at this time then use the IF SHIFT control which can help reduce adjacent frequency interference. The IF SHIFT will not reduce or eliminate all interference but it will help reduce it until you install better, more narrow, filters. Even then you may have to use the IF SHIFT and the more narrow filters to reduce and/or eliminate adjacent frequency interference. Some adjacent interference cannot and will not be eliminated with filters and IF SHIFT control especially if the offending station is operating within 500Hz to 1.5Khz of your operating frequency. If that is the case then the offending station's signal will fall within the filter's band pass and be heard. Adjusting the offending station or your frequency is about the only way to reduce or eliminate the interference.

If the 830's noise blanker is turned ON with noise present, you may experience what I call "ghost" or "phantom" interference signals. This is caused by the action of the noise limiter, opening and closing the signal path very rapidly when noise is being reduced. This is not a problem that can be fixed with tighter filtering but by simply turning the noise limiter OFF.

Use the IF Shift control until you have installed tighter filtering but remember, as I said, you may also need, at times, to use the IF SHIFT in addition to using the tighter filters to reduce and/or eliminate adjacent interference.

Bill,

Check out "Almost All Digital" at www.aade.com he's in Auburn, WA.
The frequency counter/display he has for the 520 is NOT plug-n-play, so some internal connections will have to be made....or you can go with another type...that will sample the RF signal externally.

For test purposes only, a few years back, I tried using a frequency counter connected through an attenuator, a wire wrapped around the coax cable to sample the transmitter's transmit signal. Although this did display the transmit frequency, the display is not stable because the transmit signal "level" varies. In addition, the display only displays the "transmit" frequency, not the "receive" frequency. This method is quite stable when used with an AM transmitter that has a constant carrier in transmit but, again, it does not display the "receive" frequency.

Modifications will have to be made to the transceiver if after market displays are used. Modifications will also have to be made to the transceiver if the transceiver is the original 520, whether after market or using the DG-5.

Steve,
You have perhaps the best cw rig ever with the exception of perhaps these "Starwars" rigs. I've never used one! The TS830 has been my primary rig for a long time. It is the best CW rig I've ever used. I too thought it should perform better... and it did. My problem was that I did not spend enough time learning how to use VBT and the IF SHIFT. I installed a CW filter before learning to use these controls, but now I never use the CW filter. My advice is read the I.B. and practice using the controls.
Gook luck,
Bill

I bought a function switch for my ts-520s from him last week. It got here in
barely 3 days, it was quicker than I expected.

My 520s is finally working, it was the switch this entire time.
I'm ecstatic that I'll finally be able to use it.

You can also narrow the IF bandwidth with the VBT (Variable Bandwidth Tuning) control. If you turn it counter-clockwise, the IF bandwidth gets very narrow. Not as good selectivity as with CW filters, but not too bad. You will probably have to play with the IF Shift also, to get the best CW reception, but it should reduce some of the interference from nearby signals.

Al, WA2AS

> Adjacent interference can be reduced and/or eliminated by adding better filters. If adding filters is not an option at this time then use the IF SHIFT control which can help reduce adjacent frequency interference. The IF SHIFT will not reduce or eliminate all interference but it will help reduce it until you install better, more narrow, filters. Even then you may have to use the IF SHIFT and the more narrow filters to reduce and/or eliminate adjacent frequency interference. Some adjacent interference cannot and will not be eliminated with filters and IF SHIFT control especially if the offending station is operating within 500Hz to 1.5Khz of your operating frequency. If that is the case then the offending station's signal will fall within the filter's band pass and be heard. Adjusting the offending station or your frequency is about the only way to reduce or eliminate the interference.
>
> If the 830's noise blanker is turned ON with noise present, you may experience what I call "ghost" or "phantom" interference signals. This is caused by the action of the noise limiter, opening and closing the signal path very rapidly when noise is being reduced. This is not a problem that can be fixed with tighter filtering but by simply turning the noise limiter OFF.
>
> Use the IF Shift control until you have installed tighter filtering but remember, as I said, you may also need, at times, to use the IF SHIFT in addition to using the tighter filters to reduce and/or eliminate adjacent interference.

Well he responded, rather quickly I might add, but said he only sells "parts" for the hybrids, not a partial or complete transceiver. I'll keep him in mind if I get one and need a part.

There are 2 on eBay being sold as "Tech Specials". I don't like using eBay because bidders tend to push the prices way over board making a "Tech Special" not worth the money, then there's the shipping cost added to the inflated over prices Tech Special. I should never have sold my TS-530S!! I want one I can fix that isn't going to cost as much as a new TS-2000. Oh well, I'll keep on looking. Thanks again for the tip.

Greeting Group,

I am getting more into diagnosis/repair thanks to the members of this group.
I have a/some questions:

A "slow sweep generator" is stated in the service manuals to properly adjust areas of these rigs. I am confused about the specifications, as I have a TS520s service manual in font of me..and it states that the "center frequency" should be 8.83Mhz..that I can understand..but I have looked at numerous ones for sale on ebay with various descriptions of: 2Mhz, 10, or 20+ Mhz. Is this what the unit is capable of tuning through? If one unit is say... 10Mhz...would that satisfy the 8.83Mhz BPF freq requirement?

Hi Joe,

I'm Mel. In the simple application a "slow sweep generator" can be a manually tuned signal generator plus a method of seeing the response with an oscilloscope. It is better to have a RF generator capable of sweeping at various rates. So if you are looking at obtaining a signal source, let your budget do the talking. If this is a one time effort, I would borrow one. They tend to be on the pricey side. I find more use testing having a good two channel scope and a manual RF generator. However, if you really want to get into it in a big way, you need to define the equipment you need and shop for deals. A simple test set up will run you around $500 for used equipment. 5 to 10K for new full service equipment. Having said that, I have set my shop up over the years of careful buying and can do just about any testing I need to do. Cost probably 10K, new about 35K. But then I can test anything to 12GHz.

I hope this helps.

Mel, K6KBE

Morning,

Recent posts about frequency counters (digital displays)have got me thinking about buying one for my TS-520SE.
Has anyone had experience with (or any thoughts on)the "DD-103 Universal Digital Dial" from wwww.electronicspecialtyproducts.com/dd103.html
It sells for $125.00 plus $10.00 US Shipping. It comes with a Universal Interface.
ALSO a "Plug And Play" cable is available for the TS-520 (for $15.00).

Tnx, Al, N6TEZ

Hi Joe,

I don't know what those people on eBay are talking about. They may be speaking some mythical nonsense or some other nonsense.

Here are the facts, not some half bake mythical coffee house nonsense.

First, the IF frequency in the TS-520 series transceivers is "3.395Mhz" not "8.830Mhz". The TS-530, TS-820, and TS-830 have an 8Mhz IF frequency and the method of generating and receiving single sideband is similar but different.

The various hybrid model's IF frequencies and crystal filters do NOT have a 2Mhz, 10Mhz, or 20Mhz spread!

My explanation that follows is for the TS-520 since that is the transceiver you have in front of you.

Second, the typical factory band width of the sideband filter in the hybrid models is 2.7Khz and the CW filter's bandwidth is typically 500Hz, not "2Mhz", "10Mhz" or "20Mhz". Note "Mhz" and "Khz", where "Mhz" means "Mega Hertz" (1 million hertz) and "Khz" means "Kilo Hertz" or "1,000 Hertz", there is a huge difference between the two when referring to frequencies. Your house voltage has a frequency of "60hz" which means "60 sine waves" every "second". One Mhz means 1 million sine wave cycles "every second"! The same for One Khz, 1,000 sine wave cycles "per second"!

The 520, 530, 820, and 830 all have a "variable" "TIF" and "RIF" band pass frequency between 8.895Mhz to 8.395Mhz. This frequency varies depending on the frequency of the "incoming" receive signal and the "transmit" signal frequency. There are "2" variable band pass signals, one for transmit which is referred to as the "TIF" frequency which stands for "Transmit Intermediate Frequency" and the receive "RIF" which stands for "Receive Intermediate Frequency". Now do NOT become fooled into believing the 520 has an IF frequency of 8Mhz because if you believe that then you would be wrong!

For example, lets use 80 meters and a receive signal of 3.750Mhz from Goober in Any Town, USA. A frequency of 3.750Mhz is about in the middle of the 80 meter band. The VFO is set to 275 on the dial or tuned for a digital display of 3.750Mhz on the digital display. This same process occurs on "ALL" bands except the band switch selected RF Unit heterodyne crystal oscillator frequency is different for each band.

The receive signal arrives at the COIL UNIT board from the antenna and flows through the COIL UNIT band switch selected antenna coil then on to the receiver's RF amplifier. The signal is amplified by the receiver RF amplifier then fed to the first receiver mixer where it is mixed with the 80 meter 12.395Mhz heterodyne oscillator frequency producing the following results, or as I like to call it, "the desired frequency"!

12.395Mhz - 3.750Mhz = 8.645Mhz

12.395Mhz is the 80 meter RF Unit heterodyne oscillator crystal frequency.

3.750Mhz is the frequency of the receive signal.

8.645MNhz is the first receiver's mixer output, or "desired signal". Notice it falls within the 8.895Mhz to 8.395Mhz band pass frequency range which is now referred to as the receiver's "RIF" (Receive Intermediate Frequency) signal.

The 8.645Mhz RIF signal is then applied to the IF UNIT then on to the receiver's "second" mixer where it mixes with the 5.250Mhz VFO signal producing the following results:

8.645Mhz = 5.250Mhz = "3.395Mhz"

8.645Mhz is the same "desired RIF signal" from the RF Unit's first receiver mixer

5.250Mhz is the VFO's output frequency when the VFO is tuned to 250 on the dial. The VFO tunes between 5.500Mhz and 5.000Mhz, where 5.500Mhz is the bottom of "ALL" bands and 5.000Mhz is the top of all bands! The VFO frequency range remains the same regardless of the band switch and Mode switch position.

3.395Mhz is the 520's "IF" frequency. Remember I said don't be fooled into believing the 520's IF frequency is the "8Mhz" signal! The crystal filters have a center frequency of "3.395Mhz" and will NOT pass an 8Mhz signal no matter how hard one tries to do it!

The "3.395Mhz" signal is "NOW" the 520's actual "IF" frequency which is then applied to the Mode switch selected crystal filter where, depending on the Mode setting, SSB (USB or LSB) or TUNE/CW modes, the signal flows through the filter.

The signal exits the output of the crystal filter and is then applied to the IF amplifiers where the IF signal is amplified. The IF signal is then applied to the AGC amplifier where AGC is produced and display on the meter as "S Units". At the same time the IF signal is also applied to the "GENERATOR UNIT" where it is then applied to the balanced or "ring" detector. At the same time the CAR Unit Mode switch selected crystal oscillator signal is also applied to the GENERATOR UNIT's balance or "ring" detector where it is mixed with the IF signal where the transmit station's "audio" is recovered. The recovered audio is then applied to the AF AVR Unit's audio amplifier where it is amplified then fed to the speaker where you hear, "Ok Bill, thanks for the report...".

The process is "reversed" in transmit.

Mike,
Great Tutorial. Good job explaining it. I think what Joe is asking is that in the Service manual for the 520s under Equipment needed it states: Page 45
8)

Slow Sweep Generator
1) Center Frequency 8.83 MHZ
2) Frequency Deviation Maximum +/- 5 KHZ
3) Output Voltage more then 0.1 Volt
4) Sweep rate at least .5 sec/cm

73,
Gordon

Mike,

Just for my edification, what is a 'tech special' ?

I have an 830s 'Gold' (original owner, works great), meaning it has the gold 'TS-830s' label. The gold label radios are supposed to have some filters, etc standard. I do have a narrow cw filter, but that may be on all 830s's.

A truly great radio.

A tech special is a radio that needs work in order to make it usable. Great for those with the technical knowledge to fix them and usually at a lower cost.

Subject: [TS-520_820_530_830] Re: TS-830S

Mike,

Just for my edification, what is a 'tech special' ?

I have an 830s 'Gold' (original owner, works great), meaning it has the gold 'TS-830s' label. The gold label radios are supposed to have some filters, etc standard. I do have a narrow cw filter, but that may be on all 830s's.

A truly great radio.

A TECH special is a radio that has a problem that is difficult to diagnose or repair...beyond the capabilities of a casual tinkerer
.

Good morning Dick,

Jim and John both provided correct answers to your "Tech Special" question.

Some radios, such as the Kenwood TS-430, TS-430, Yaesu FT-757GX/GXII and other similar CPU controlled radios that are advertised as "Tech Specials" require an thorough in-depth knowledge and understanding of digital control circuit technology in order to diagnose and make repairs.

Al,

Go here for some useful info on the AADE digital display for the TS-520 series:

http://www.aade.com/C520/C520.htm

As I understand the DD-103, for the 520's you have to tell the unit which band the rig is on.

The AADE does a nice job with the 520S and 520SE. It utilizes the three signals at HET, OSC, and VFO on the back panel of the rig to calculate the operating frequency. It also shows the mode of the rig. All automatically.

I have modified the AADE unit for my 520SE to send the operating frequency to logging programs (MixW, N1MM, etc.).

Topic: 29220 Message: 29220

Dear Group;

I recently bought a YG-88C for my TS- 820 and put it in. I tried the jumper on the IF board in both other positions - meaning position "B" and "C"- with the same result: signals are attenuated so much I cannot hear anything; the receiver is essentially deaf. When I switch to any other mode, like USB, I can hear all kinds of strong signals.

Anyone have advice? Is it possible the filter was DOA? Bad Soldering job (it looks pretty good)? something else?

Thanks;
Jacob K4JQV

Dave,
To adjust the RIT control, you do it with the VR2 on the AF board
Be sure that you did Step3 in the service manual where you adjust VR2 on
the PLL board so that the Rx and TX frequencies are the same.
I use a Freq Counter on TP3 of the IF board to measure as I adjust VR2
on the PLL board until the TX and RX are the same.
Hope that helps.

They should not , if they are off unless one of the switches is bad.
How far off is the RIT? and is the Knob on correctly?
It can be inserted in many positions, but only one is correct to give
you no change when pushing in the button.
Centered in its travel the line should be straight up.

RIT knob is centered and in the middle of it's movement. RIT switch is OFF. When I turn it ON and the LED lights up I can tell a difference so looks like it's working OK.
I did Step3 in the service manual where you adjust VR2 on the PLL board so that the Rx and TX frequencies are the same. I used a Freq Counter on TP3 of the IF board to measure as I adjust VR2 on the PLL board until the TX and RX were the same. But I'm still off from Xmit to Rec. So.... What else could it be?

Mike,
Great Tutorial. Good job explaining it. I think what Joe is asking is that in the Service manual for the 520s under Equipment needed it states: Page 45
8)

Slow Sweep Generator
1) Center Frequency 8.83 MHZ
2) Frequency Deviation Maximum +/- 5 KHZ
3) Output Voltage more then 0.1 Volt
4) Sweep rate at least .5 sec/cm

Dave,

Did you also perform step "7" "VFO, RIT, FIX CH check and adjustment"? If not then you should also perform step 7.

The RIT control varies a DC voltage (9VDC) from the AF Unit's 9VDC supply, through AF Unit plug 7 pin 9 (RIT, to the RIT pot. When RIT is enabled and the RIT control is rotated CW or CCW, the 9VDC applied to the VFO plug pin 2 (RIT) varies the voltage applied to varicap diode D2. By varying the voltage to D2 the capacitance of D2 changes resulting in a change in the VFO's output signal without touching the VFO knob. The relay on the AF Unit disables the RIT know in transmit allowing the VFO to return to it non-RIT adjusted frequency. Turning RIT off disables the RIT control whether in receive or transmit.

Step 7 says to adjust the VFO for a VFO output frequency of 5750Khz, center the RIT control, turn RIT ON, then adjust VR2 on the AF Unit so the VFO output frequency is 5750Khz with RIT ON and OFF. This should solve you slight off frequency problem.

29228. ts-820s service manual

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Hi Folks,
I am new here but looks like a great place for anyone using the hybrids. I am looking to buy a ts-820s service manual, not a PDF file but a real honest to goodness paper manual. Does anyone have one or know where I may be able to find one. Any help would be greatly appreciated. Thanks and have a good new year.

29230. Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-08 22:07:07 UTC
From: roberteleazer@rocketmail.com
Topic: 29230 Message: 29230

Gentlemen, I have a problem with my TS-820S and seek your opinions.

I had my 820S all adjusted, installed a new INRAD SSB filter, ran INRAD's recommended tests and all was looking good. Power output on CW was 90W into a dummy load on 160 □ 20 M and rather less above that.

Then last weekend the digital display went screwy. I confirmed that it was just the display, removed it and cleaned all the contacts in it and put it back together. The display was fine then but I found the rig was not receiving, and after a few minutes it blew the main AC fuse. I opened it up, found that the most forward connector to the driver board had come partially loose during the previous work. I plugged that connector back in, put in a new fuse and everything is almost right again.

Thing is, the rig acts like the finals have gotten weak all of a sudden. Best CW output into the dummy load is maybe 60W. The Plate current indication is low, commensurate with the measured RF output. HV is 840V. ALC is fine in Tune and CW. I am wondering how the loose plug problem may have caused this.

Any ideas?

Thanks!

Robert

If the RIT is centered and you push the RIT switch, you should NOT hear
a difference. The Freq should be exactly the same. That is why you
adjust VR2 so they are.
When the RIT is on, rotating the RIT knob should make a difference but
centered, it should be the same whether RIT is on or Off

Hi Mike. I have a TS-530S that has an odd problem. When the RF Gain is rotated clockwise past about 8, the RX drops off somewhat. Everything else works pretty well. Cosmetically its about a 6-7 out of 10. A few marks on the face, and a few larger ones on the case halves. It may need aligned. I have 3 NOS GE 6146B and 2 NOS 12BY7A tubes. No mic included.

If you are interested, I will sell it for $175.00 shipped. I can take some pics an send them to you if you are interested.

Morning Robert,

What are the IP and HV meter indications when the 820 is producing 60 watts output?

When tuning for a peak ALC indication in TUNE mode is the meter indication stable or does it slowly or otherwise drop back toward zero once you achieve a peak DRIVE control ALC indication?

Good Morning Group:

This is a follow-up to my earlier post regarding the TS-820S.

I would certainly be interested in comments from the group, regarding improving on an already terrific transceiver. What enhancements or mods (if any) are considered most desirable?

I look forward to all constructive commentary.

29238. TS 820 VFO has busted a gut

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-09 05:41:10 UTC
From: jacob
Topic: 29238 Message: 29238

Hi;

I cleaned my VFO as others here suggested which solved my chirp problem. Thanks!

But, some days later I turned the bezel behind the main tuning knob - to sync the sub dial to the digital display- but in a fit I turned it too far and something popped. Now the main tuning dial encounters resistance at one point while turning. I looked with a flashlight - with the case off - and it turns out one of the small split gears has half a spring sticking out (this hits the VFO shaft and makes the resistance). Anyone have luck fixing such a mess?

Help please.

Best;
Jacob

29239. TS 820 vs TS 820S manual - the same

From: roberteleazer@rocketmail.com
Topic: 29230 Message: 29240

Good afternoon, Mike:

The HV indication is about 840V but I think that after a while, following repeated short transmissions, it may go down to perhaps 820.

IP at 60W CW is about 120MA. And there is very little "dip" when tuning the plate. My first thought was that the short somehow took out one S-2001A. I have a spare but need to figure out which one might be bad before doing any swapping.

The ALC indication on transmit for Tune and CW modes is very strong at peak, pegging the needle to the right when the Drive control is properly adjusted. On SSB modes there is much less ALC indication, but there is some there. There is no decay in ALC as transmit goes on, so I assume the driver tube is good.

And yes, it sure sounds like power output is commensurate with Ip and voltage indications. I think the HV is lower than it used to be. I believe it was formerly up around 900 where it should be.

Perhaps that short that blew the fuse damaged the power supply. But it did not damage it too much, which sounds odd. I guess it could be a rectifier diode that is not quite doing the job. A total loss of HV due to that short would be believeable but a fairly small partial loss is not a failure mode I can explain right now.

I suppose that the HV caps getting old could cause a decrease in HV but why that would be apparantly associated with that loose connector and the short I have no idea.

I am going to go look at the manual and see what the HV should be at various points and maybe take some measurements.

Shucks! I was looking forward to setting this rig aside and working on an NC-155 where I need to rebuild the 2nd local oscillator.

I would appreciate any thoughts!

Best regards,

Robert

Here it is has been done the same way for years and years.
TS 520 and one of 3 model 28 ASR's. No added filtering.

Hi Joe. I have used a TS-530S on PSK31. I Had only the standard SSB filter (YK-88S) installed. I used a very simple interface that connects the headphone output of a laptop to the mic plug on the radio via a 20:1 audio transformer, and that connects the headphone jack on the radio to the mic input on the laptop via another 20:1 audio transformer. I had the 20:1 transformers in the junkbox, and they save me from needing any attenuation. I used VOX to key the radio.

This setup worked very well, still does with my TS-130SE and TS-430S. I used Digipan on a Compaq P133 laptop with Win98se and 32 meg ram. I now use FLdigi on an IBM T41 with 512 meg ram, P4 1.6 Ghz, running Aptosid GNU/Linux with the same interface.

Afternoon Robert,

The only plug on the RF UNIT, the board you are referring to as the driver board, that can cause the fuse to blow is RF2.

RF2 has 4 pins that can affect the driver and both final tube's bias voltage, pins 7 thru 10. If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!

If you have a set of known good driver and final tubes then I recommend using them then test for power output. I also recommend checking and, if necessary, replace the 2 cathode resistors, R5 and R6 both 10 ohm 1 watt. If these increase in resistance, for example, the current flow through the final tubes will be "less".

I doubt the problem is the HV supply.

Mike:

Ran some more transmit tests and here is what I found.

When I fired it up this time on 20M I could get about 80W on CW, less than before but still pretty good.

With SG 0ff the HV was 900V. With SG on it was about 800V. Sounds pretty good.

But as I let the set run it deteriorated. It was never been as good on output on the other bands as it was on 20M, but 80M was noticeably down from before.

And after letting it run for a couple of hours or more with occasional short transmits the power output got worse. HV under load deteriorated down to maybe 780V.

The funny thing was that on 20M as you let it transit the Ip would go up with time and stay up.

I will let it cool down and try it again to see if power is back up.

And I will check to see about those resistors you mentioned and plan to put another set of finals in. The HV deterioration with time sounds like the HV caps are getting old.

Thanks!

Robert

Greetings Mel,

Tnx fer your info. I really don't want to spend big bux on something not in use all the time. There are a couple of units on ebay that are relatively cheap and carry well known names, Wavetek and BK for two. I am just wondering how to properly adjust the BPF (band pass filter) for TX & RX. Some of this stuff is new to me.

Subject: Re: [TS-520_820_530_830] test equipment

Hi Joe,

I'm Mel. In the simple application a "slow sweep generator" can be a manually tuned signal generator plus a method of seeing the response with an oscilloscope. It is better to have a RF generator capable of sweeping at various rates. So if you are looking at obtaining a signal source, let your budget do the talking. If this is a one time effort, I would borrow one. They tend to be on the pricey side. I find more use testing having a good two channel scope and a manual RF generator. However, if you really want to get into it in a big way, you need to define the equipment you need and shop for deals. A simple test set up will run you around $500 for used equipment. 5 to 10K for new full service equipment. Having said that, I have set my shop up over the years of careful buying and can do just about any testing I need to do. Cost probably 10K, new about 35K. But then I can test anything to 12GHz.

I hope this helps.

Mel, K6KBE

Subject: [TS-520_820_530_830] test equipment

Greeting Group,

I am getting more into diagnosis/repair thanks to the members of this group. I have a/some questions:

A "slow sweep generator" is stated in the service manuals to properly adjust areas of these rigs. I am confused about the specifications, as I have a TS520s

service manual in font of me..and it states that the "center frequency" should be 8.83Mhz..that I can understand..but I have looked at numerous ones for sale on ebay with various descriptions of: 2Mhz, 10, or 20+ Mhz. Is this what the unit is capable of tuning through? If one unit is say... 10Mhz...would that satisfy the 8.83Mhz BPF freq requirement?

When you measure the HV is the 820 keyed with the SG switch ON and OFF? The only way the HV meter switch setting with display HV is in transmit. In receive the Relay Unit relay terminals disables all meter switch settings and the meter displays receive signal strength, S Units, ONLY.

A more accurate method of measuring the 820's HV is to measure the HV at the Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do this if you are tired, being disrupted or distracted, as you can easily receive a severe electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800 terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least 1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise you can easily burn out your meter!!!

It is possible the HV filter capacitors are quite leaky due to age and previous usage. If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.

Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

John,

I have used my TS-530 on PSK for the last few years. The internal VFO drifts a little so I added a VFO-230. A minor modification was made to the radio to use the 500Hz CW filter in USB mode. This is not essential but it helps when there are strong signals on the band.

The interface to the computer is homebrew. The interface is plugged into the external speaker jack on the back and has an audio amplifier to drive another speaker. This enables adjustment of the external speaker volume independently from the audio level to the computer.

I puchased this tv-506 (6 meter transverter), from a fellow ham about a year ago, it works perfectly and has the connecting cable and manual. It had been my intention to acquire an ts-820s to use it with. Things change though and I am no longer going to do that. It is in perfect condition and has no rust, smoke enviroment, dents,scratches, etc. --- the bottom left hand cornor of the front edge has a slight 'mar', not a scratch, other than that it is perfect and will be guaranteed not to be DOA.
The shipping weight in a bubble wrapped and popcorn filled box is right at 15 pounds and I will send it via USPS or UPS, your choice. I want $200 plus $20 shipping for it, paid with a USPS money order. You can contact me at ke7kly@.... If I don't sell it in the next few days it will go on to eham and then ebay.

Mike:

First, with the SG switch off and with the key down I get 900V on the HV meter setting and with the SG switch on I get 850V to 750V, depending on output, band and which finals I have installed.

I took out the S-2001A's and put in two 6146's ☐ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!

I have not yet run the neutralization procedure on these tubes. I guess I will do that next.

I have checked the HV before on the 820S using a PSM-45 DVOM, so i know how to do that.

I think that I also will try the 6146B's that originally came with the rig. I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to see how the B models will do in the 820S.

Thanks!

Robert

strength, S Units, ONLY.
>
> A more accurate method of measuring the 820's HV is to measure the HV at the Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do this if you are tired, being disrupted or distracted, as you can easily receive a severe electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800 terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least 1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise you can easily burn out your meter!!!

If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.
>
> Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!

29254. Re: Sudden Decrease in TS-820S RF output

Robert,

I assume the 250ma is in CW mode with 750VDC showing on the HV meter and well over 100 watts output. If that's true then power input would be

750 x .225 = 187.5 watts DC input

That's 27 watts higher than the 820's designed CW mode 160 watts DC input power rating. Based on 55% efficiency input to output of the Class AB1 final amplifier that would equate to approximately 142.5 watts output.

If you have a known good pair of 6146Bs, install them, check for 60ma of no signal idling current in USB or LSB mode, it doesn't matter what band has been selected, then retune the 820 into a dummy load.

A known good 12BY7 driver tube can produce more than enough drive to the final tubes for a full scale ALC indication when adjusting the DRIVE control. The ALC peak in TUNE mode should be stable, not drop back toward zero on it's own.

Power input tuning should be smooth and full output should occur at the same point as maximum IP dip. If these 2 things do not occur at the same point then the final amplifier needs to be neutralized.

I would not operate the 820 with an RF output of more than 110 watts as that can easily over stress the power supplies and shorten the life of the final tubes.

The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

73s
Mike

29255. Re: Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-11 13:33:50 UTC
From: roberteleazer@rocketmail.com
Topic: 29230 Message: 29255

Mike:

No, the 0.25 amps is in USB mode with 90W indicated on the MFJ tuner meter. For CW the Ip is even higher with indicated output over 100W. For USB that is .250 X 800V = 200W. Impressive but kinda scary!

I plan to do two things:

1. The alternate alignment instructions I used had you adjust not only the Drive coil on the RF board but also a coil on the IF board (I'm at work now and dfo not have my manuals so I do not know what teh designation of that coil is). As a result in CW and Tune modes on 80-40-20 in Tune or CW the ALC indication pegs the needle with the Drive control peaked. Setting the Drive coil helped ALC a lot but the coil on the IF board really maxed it out. I plan to back off on that coil on the IF board a bit.
2. I am going to neutralize the tubes as I did the last time, by turning the SG Switch Off, running the output to my oscilloscope, and Teeing off from that to a dummy load, key up, then tune for minimum voltage. Before, given the sensitivity of the scope, I found that I could neutalize the rig right down to nothing, with no output with the SG switch back on. We will see this time.

True, I do need to check idling current with these new tubes.

Also, I would like to see how the 6146B's I have perform. I do not have any known good 6146B's but have a number of mainly used 6146's, one probably good S-2001A and I think a set of 6146A's that may be good.

And I guess I could run the INRAD alignment procedure again as well. Would be interesting to see how with the new tubes output power varies with the freqs applied to the mike input and the Mike level.

Thanks again!

Robert

If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.
> > >
> > > Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

Yes, I agree, especially the CW IP current being much higher.

The first step in transmitter alignment is on page 49 of the 820 service manual titled

"4. Adjustment of Transmitter Section".

This step states to adjust "T10" on the IF Unit board. T10 on the IF Unit board is the "balance modulator" transformer. The Mode switch is set to "CW" and the CAR control set to 12 o'clock in order to provide an RF carrier which is not possible in USB or LSB without applying audio to the speech amplifier. The step does not state whether to have a CW key plugged into the CW socket or not. I recommend removing any CW key from the CW socket as this will allow the SEND switch, when flipped "UP" to key the transmitter and produce output. The CW socket is a "Normally Closed" socket so a CW key is not required in the CW socket during this transmitter alignment step.

The 820 is keyed and T10 is adjusted for maximum 8Mhz "TIF" signal appearing at the IF Unit's plug IF3 pin 2 "TIF" terminal. This alignment step does not mention this but that's is what the adjustment of T10 on the IF Unit is for. The "TIF" signal is then applied to the RF Unit plug RF1 pin 1 where the "TIF" signal is applied to RF Unit transmit mixer transformer T1. T1 is adjusted for maximum IF Unit TIF signal transfer to the transmit mixer. The step also does not mention this but that is what T1 on the RF Unit is for, maximum TIF signal transfer to the transmit mixer.

The step further states to adjust the "DRIVER" coil for maximum "ALC" indication. This is done for each band but the adjustment for each band driver coil is performed in a specific sequence (Fig 2.3 COIL PACK adjustments). This adjustment provides for maximum signal transfer (resonates the driver tube's PLATE circuit on the specific band) from the driver tube through the COIL PACK "DRV" terminal to the FINAL UNIT "DRV" terminal. The DRIVER coil

pack adjustment serves 2 purposes

1. Tunes the driver tube's plate circuit for the band selected
2. Acts as a tuned input to the final amplifier

> 2. I am going to neutralize the tubes as I did the last time, by

Yes, I agree, checking and if necessary, perform the neutralization steps. This will stabilize the final amplifier plus allow the plate DIP and max power OUTPUT to occur at the same time, resulting in a more accurate HV and IP tune up indication which is what the transmitter tune up should be.

>
> True, I do need to check idling current with these new tubes.

This should be done first before performing any transmitter alignment steps. The final amplifier bias must be set to it's normal Class AB1 no signal idling current first, regardless of out much, if any, the transmitter alignment adjustments are out of alignment.

> Also, I would like to see how the 6146B's I have perform. I do not

> may be good.

One weak final tube out of two can easily exhibit a hotter glass envelope than the other, especially in your case. There is no way to determine which one is weaker by simply monitoring the IP meter display in transmit. The final amplifier operates in parallel and the IP meter current level is a combination of final tube screen and plate currents. The IP meter indication is displaying the final tubes "cathode current" which is the "safer" method to display plate current. In the old days a meter was connected in "series" with the final amplifier's HV supply.

> And I guess I could run the INRAD alignment procedure again as

I'm not familiar with INRADS alignment procedures. Therefore I can't comment on them.

>
> Thanks again!
>
> Robert

I provided additional technical information so one understands "why" the adjustments are performed. The alignment steps do not mention this. It's better to know why one does something than rather to simply "do it and look for this..". My comments are not meant to be disrespectful but rather to help one to understand what the adjustment does and why.

> >
> > The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

> > >
> > > I took out the S-2001A's and put in two 6146's ï¿½ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!
> > >
> > > I have not yet run the neutralization procedure on these tubes. I guess I will do that next.

I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to see how the B models will do in the 820S.

> > > >
> > > > A more accurate method of measuring the 820's HV is to measure the HV at the Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do this if you are tired, being disrupted or distracted, as you can easily receive a severe electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800 terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least 1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise you can easily burn out your meter!!!

Update: both Mouser and Jameco have replacement IC's. Anyone else running into this situation should look under "Texas Instruments, CMOS Dual Up-Counters" and part numbers CD4518B, CD4520B.
I ordered a few from Mouser only because they are T.I. parts. Jameco listed the manufacturer as "manufacturer may vary." They are cheaper at Jameco but I went with T.I. due to their reputation.
Hopefully, I'll never need to use them but at least I'll have 'em!

I'm new to hybrids, so please be kind. Anyway, how does one go about setting the rig to run at less than full power? I've read the manual several times, searched postings here and at e.ham but, so far, keep coming up empty. I read a posting on how to do this about a year ago, but I didn't have the 520SE then and, naturally, I can't find the posting now.
If I wanted to put out a signal at 50 watts what exact steps should I be following? Please advise.

Hello Charlie,

You didn't say what Mode you intend on using and for what purpose, such as PSK-31, RTTY, SSTV, or normal sideband or CW operation. Knowing which mode will help use help you and your desire to operate at a lower power output level. Until we know what mode you will be operating in, the following is a simple explanation how "normal" power output is controlled in the various modes the 520SE operates in.

Normal power output in USB or LSB Modes is controlled by the "MIC" gain control. This controls the level of audio from the microphone amplifier to the balance modulator.

Normal power output in TUNE/CW mode is controlled by the "CAR" control. Power output in CW mode can be set to 50 watts output.

29260. New to Ham radio. Is the TS-530S a good place to start?

I am studying for both the Tech and General license. I have no communications or electrical training. I am a licensed automotive mechanic, but haven't worked in that industry in years. I am now an Operations Manager (mostly marketing, payment systems technology, etc.) Bascially, I'm very IT saavy and good with my hands (soldering and desoldering is getting better every day!). I am more of a hands-on learner and know enough to know when I don't know enough.

I understand that the TS-530S is not a plug n'play solid state unit. But I am on a PC and Blackberry all day long and would prefer something more manual in design. Also, by having to tune the TS-530S each time I change frequencies, etc., I believe I'll learn more about the radio's function at a faster rate, than say an ICOM 718. I have had my fair share of hobbies: RC Cars, model trains, and in fact whip up my own cream and wet-shave every day (you have to try that!). In my mid forties, I find I want to slow some things down, enjoy them more, etc.

My questions are:

1 - do you recommend the TS-530S as a first radio?

2 - Are my assumptions about learning on the TS-530 incorrect?

3 - Do these units have specific eqipment requirements, with regard to antenna, etc., or can I start with very basic equipment and go/grow from there?

I'm really looking to better understand radio, electronics, etc. as a hobby. Don't laugh, but I actually baught, well Santa brought me, a Radio Shack Electronics Lab, with the Workbooks written by Forrest Mimms. Rudementary to many of you, but I needed to start with the basics.

I have been perusing K4EAA's site as well. I also picked up an inexpensive 2 meter mobile, and two HTX-202s that were new in the box. Straight 2 meter units.

Thank you in advance for any advice.

29261. Re: TS-520SE IC part supplier?

Charles,

Binary up counters are manufactured by a number of different companies. The important thing is to ensure the chip is the same binary up counter with same or very similar voltage specifications and same pin designations. IC chips are almost all made in China, Taiwan, or other foreign countries and companies such as Toshiba and Texas Instruments simply have their name put on the chips. There are very few, if any, IC chips made in America.

29262. Re: [TS-520_820_530_830] Re: Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-11 17:05:32 UTC
From: John Davidson
Topic: 29230 Message: 29262

where is your loading capacitor set>?
On 80 M my 520 loading capacitor is set nearly all the way CCW to get 200 mA Ip dip at 100 W output.
I'm sure it is farther clockwise on the higher bands but it has been a few years since I went off 80M

Subject: [TS-520_820_530_830] Re: Sudden Decrease in TS-820S RF output

Mike:

No, the 0.25 amps is in USB mode with 90W indicated on the MFJ tuner meter. For CW the Ip is even higher with indicated output over 100W. For USB that is .250 X 800V = 200W. Impressive but kinda scary!

I plan to do two things:

1. The alternate alignment instructions I used had you adjust not only the Drive coil on the RF board but also a coil on the IF board (I'm at work now and dfo not have my manuals so I do not know what teh designation of that coil is). As a result in CW and Tune modes on 80-40-20 in Tune or CW the ALC indication pegs the needle with the Drive control peaked. Setting the Drive coil helped ALC a lot but the coil on the IF board really maxed it out. I plan to back off on that coil on the IF board a bit.
2. I am going to neutralize the tubes as I did the last time, by turning the SG Switch Off, running the output to my oscilloscope, and Teeing off from that to a dummy load, key up, then tune for minimum voltage. Before, given the sensitivity of the scope, I found that I could neutalize the rig right down to nothing, with no output with the SG switch back on. We will see this time.

True, I do need to check idling current with these new tubes.

Also, I would like to see how the 6146B's I have perform. I do not have any known good 6146B's but have a number of mainly used 6146's, one probably good S-2001A and I think a set of 6146A's that may be good.

And I guess I could run the INRAD alignment procedure again as well. Would be interesting to see how with the new tubes output power varies with the freqs applied to the mike input and the Mike level.

Thanks again!

Robert

The TS-530 and related radios are hybrids. They are primarily solid-state but use a few tubes in the transmitter. It will teach you about tuning a tank circuit, but it's not a true tube radio.

An all-tube radio will teach you more, but you might not like the lessons. At least not at first. The learning curve is steep and these radios are much older and usually require a good deal of work and adjustment due to age.

The TS-530 is easier to operate than most all-tube radios, mostly because it is frequency-stable once it warms up and it has a digital frequency readout. Many older all-tube radios tend to drift, unless it was a very expensive radio in its day.

The TS-830 has a more advanced receiver, and that's a good place to invest money. Your ability to hear a signal is more important than your ability to be heard.

The required antennas aren't unique, but since we're talking about HF you should be aware that HF antennas are huge. The best place to start is with a simple wire dipole. If you want a multi-band dipole use a fan dipole. There are other wire antennas like the G5RV that are multi-band and work well too, but aren't as simple as a dipole. Most people build their own wire antennas like the dipole and G5RV but you can get them pre-made or as kits too.

Good luck and enjoy!

What ever you do to prepare for the amateur radio license exam, I recommend you actually study the license material. Don't be fooled into "memorizing" questions and answers just to pass the test. You learn absolutely nothing doing that.

I recommend you spend a few dollars and buy an older ARRL handbook, a version in the mid 60s will do. Start at the beginning, learn about resistors, capacitors, inductors, how to computer resistance in series, parallel, series/parallel, and how current flows in a resistor. Learn basic ohms law, I = E/R, R = E/I, E = I x E, and Pin = I x E. You will use these basic ohms law formulas every time you troubleshoot simple or complex problems in any piece of electronic equipment. You can pick up the older ARRL handbooks on eBay.

I also recommend purchasing the following book;

BASIC RADIO COURSE by John T. Frye

This book is out of print but quite often be found on the Internet, even Amazon.com or possibly at your local library. This book is written for people who have no electronic training and covers the basics, atoms, electrons, resistors, capacitors, inductors, ohms law, and vacuum tube including the various "types" of vacuum tubes, Diode, Triode, Tetrode, and Pentode and how each element is used to allow electrons to flow within the tube.

Do not rush to the advance topics until you have a thorough understanding of the basics! Jumping head first into advance and more complex circuits is a common mistake made by new hams. You can't run until you learn how to walk or you can't learn to swim by jumping into the deep end of the pool, you'll drown faster than you will learn how to swim!

While computer knowledge such as networking, network operating systems (NOS) and computer operating systems such as Windows, Linux, and Apple OS, along with digital electronics, for example, OR, AND, and NAND gate functions is good to know, these areas are applied in more advanced electronics AFTER you learn the basics.

Last but not least, what ever transceiver you decide to buy, make sure the manual comes with it. Read the manual "thoroughly" so you learn how to operate the radio, the warnings, if any, that you must follow, and how the features are used. More often than not many problems that pop up are "operator error" caused by not reading and understanding the manual. If you purchase, for example, a Kenwood TS-530S but there is no manual, no problem, you can download it from the following website, "free".

www.n6wk.com/kenwood/

In fact, if you want to read about any of the Kenwood hybrids you can download all of the manuals, both operator and service manuals, at the above link. Again, I can't state it enough, read the manuals so you have a thorough understanding of how to operate the transceiver. If you have questions about what is presented in the manual, come here and ask, that's what we are here for, to help YOU. There are a lot of "myths" floating around the ham community. Learning from people who are here to help you is how you learn how to "side step" those myths.

I thank you both and welcome additional comments.

Actually, electronics, studying what resistors are, Ohms law, etc. is where I started and why I bought the Lab. I had a light blinking and a buzzer sounding - wife was not very impressed ;) My dad's 1969 Military manual on electronics and a 1990 Radio Shack book by Mimms on electronics were a great introduction. The military manual does touch on tubes as well. But I'll look up the books you recommended. Used book stores have nothing, since guys probably hang on these for reference.

I have the new ARRL Technician's Manual and am reading through that as well. I admit, I was tempted to learn the answers, just to get on the air with the 2 meter and be better connected with our local club. I've slowed myself down and will meet with them, when they convene again.

I do agree about the advanced topics and have no intention to connect a PC to a ham radio for a long time. Honestly, I'm trying move away from the PC for a bit.

I am familiar, at least with the dimensions and functionality of the GR5 series antenna and that's about as "big" as I want to go. I was actually thinking attic antenna, for a while anyway. My wife is worried that I'll be wearing a colandar hat and tin foil! She needs a sense of humor to tolerate my hobbies...

Who can blame here? Right now, I have a mobile Hustler antenna mounted on a cookie sheet in my car for 2 meter reception. New cars are not very gutter mount friendly, but the antenna was free. I guess I am a little crazy...

If you are interested in mobile operation you might consider a magnetic mount 2 meter vertical. Mounting it in the middle of the roof gives you 360 degree radiation pattern using the car's roof as the "second" half of the antenna. The nice thing is there are no holes to drill and it can be removed rather easily when needed.

HF is another story.

If I may also suggestion something else. Take the license exams one step at a time. Quite often people tend to jump head first and take the Extra Class exam. By starting at the Technician level you can gain experience not only in VHF and above but also CW on HF in the frequency allocation for the Technician license. The Technician class license can also operate sideband on 10 meters.

I can't stress enough the importance of taking your time, starting at the beginning level, gaining experience and knowledge on how to operate. Read the exam study guide section that discusses about operating and read the FCC's part 97 Rules and Regulation, avialable from ARRL in pdf form plus download the Amateur Radio band color chart also from ARRL and study it. Remember, when you sign the license application you are telling the FCC that you understand and will abide by part 97 of the FCC Rules and Regulation that govern Amateur Radio. I started as a Novice many years ago, 1966, and took it one step at a time. It's not an easy task but if you stick with it, study, ask questions, then and only then will you honestly be prepared to take the exam.

If we can help, regardless of how silly you may think your question may see, don't hesitate to ask us here. We are here to help you, not make fun or talk down to you. Other ham forms may do that but not here!

I spent 15 years as a computer and network support technician professional working for a Fortune 500 company plus 10 years prior to that, in computers, as a hobby when computers first began to be sold as "home computers" (Radio Shack TRS-80 Model 1, 3, 4 and 4P). Therefore, I know what you mean by wanting to get away from it for awhile. I'm retired now, 62, and spend a lot of time here and operating on 40 meters CW. Since there is no requirement for CW in the exam, you should hold off learning CW until you get your feet wet by studying and passing the exam.

in concrete. He's been out of it for quite a while though.

Thanks, You've already been more cordial than some.

I am looking for a magnet antenna, but he passed that Hustler on to me, so I gave it a whirl. I was hoping the cookie sheet would bounce, just as the roof does, and it doesn't work half bad with my HT.

Thanks for the info on the chart. I have found another, but it wouldn't expand to more than 30% and my eyes aren't that good! ARRL's is excellent.

I was thinking of the Tech and General at one time, only because of the timing of courses, etc. Plus, others have said that the tests are somewhat similar. I'm really not in a rush to gain access to the additional freqs that General, or even Extra provide. I was just looking to pass the first two classes, while everything was still fresh. This was going to be my first hobby where I didn't put the cart before the horse. Although, I am very tempted by that TS-530S...

You are not crazy Just like a bunch of old F----s were many years ago. Its a great hobby and with guys like Mike to guide you it will be a blast. I have been at it since 1965 and in my honest opinion the older rigs are of a higher quality than a lot of the newer ones.
As far as the 530S is concerned I think it is one of the best ever made. Just need to read and understand the man. before attemting to use it. I am a boat anchor nut and love to build antennas. If I can ever be of help just let me know.
Welcome to the group. A great place to be they have helped me a bunch.

I am trying to repair my faithful TS530sp which has stopped receiving, possibly due to being on receive when too near another of my transmitters. I am looking for a source to buy things or their equivalents such as 3sk71,2sk125 etc.
Also what wattage soldering iron would be best for this rigs repair? Th one I have at the moment is 30 watts but the tip might be too thick.
Regards Jon

Jon,
Check the 1.8 Coil for the Antenna coils on the RF board.
It is usually the first thing that goes due to Static buildup or a close by TX
I have replaced or re-wound many of them.
I think it is L-41 on the 530, same as the 830

73,
Gordon

Keep us updated Jon,
It isn't always L-41 but thought I better mention it.
Does it hear really strong stations still? just low in signal level?
does the CAL work?

Hi Gordon, The calibrator works fine, but not even loud stations. last week the fixed attenuator stopped working but the variable was OK. Then the RX just went to sleep. I'll keep you up to date when I start fixing it with my new eyes. GRIN

Okay,I didn't realize that there were that many variations. Interesting. I work SSB and hope to get back into CW after I pass my Extra exam in March. I don't use any other modes. It seems that I've managed to forget most, if not all, of my characters over the years and will pretty much have to start from scratch. Oh, well...

Topic: 29230 Message: 29276

Mike:

I tried out the 6146B's and things look less dire.

The lowest Ip current I can get, with the mode switch in "Tune" and working into the dummy load, is 70ma. That is with the Ip bias control on the back turned as low as it will go and the Mike and CAR controls all the way to the left.

Undipped max Ip in transmit is 230 ma. Dipped, it is 210 ma for both USB/LSB and CW. Indicated max power for SSB is 75W with the mike unplugged and about 108W for CW. All this is into the dummy load in the MFJ tuner or switched into my Heathkit Cantenna.

The 6146's are different from the 6146B's, I know, but I would not have expected higher power out from the 6146's. Then again maybe the 6146 I have are much fresher unusued tubes that are the 6146B's. People say not to use 6146B's in older rigs and even in TS-520's but I understand they are preferred for the TS-820.

I have not run the neutralization procedure yet. That is next, since the rig does not appear to be in danger of melting from too much Ip and RF output.

By the way, the alternate transmit alignment procedure I used says to adjust T1 on the RF board for max ALC reading and also to adjust T5 (not T10) on the IF board for max ALC. In my case T1 on the RF board helped a lot but adjusting T5 on the IF for ALC peak also made a big difference - really pegged the meter.

As for the INRAD alignment procedure, they say to inject a 1K audio signal into the mike input, adjust the mike gain to get 50W, and then switch the audio signal generator to inject first a 350 HZ and then a 2.5 KHZ signal into the mike input and make sure that the power output levels are the same at 350 and 2500, by adjusting the carrier freq. They say do this for both USB and LSB. In my case I found that aligning the coil pack beforehand took care of any difference I had found so I did not have to mess with the carrier board freqs. I suspect that with a tighter SSB filter than the stock one you might have to do that.

Thanks!

Robert

> The first step in transmitter alignment is on page 49 of the 820 service manual titled
>
> "4. Adjustment of Transmitter Section".
>
> This step states to adjust "T10" on the IF Unit board. T10 on the IF Unit board is the "balance modulator" transformer. The Mode switch is set to "CW" and the CAR control set to 12 o'clock in order to provide an RF carrier which is not possible in USB or LSB without applying audio to the speech amplifier. The step does not state whether to have a CW key plugged into the CW socket or not. I recommend removing any CW key from the CW socket as this will allow the SEND switch, when flipped "UP" to key the transmitter and produce output. The CW socket is a "Normally Closed" socket so a CW key is not required in the CW socket during this transmitter alignment step.
>
> The 820 is keyed and T10 is adjusted for maximum 8Mhz "TIF" signal appearing at the IF Unit's plug IF3 pin 2 "TIF" terminal. This alignment step does not mention this but that's is what the adjustment of T10 on the IF Unit is for. The "TIF" signal is then applied to the RF Unit plug RF1 pin 1 where the "TIF" signal is applied to RF Unit transmit mixer transformer T1. T1 is adjusted for maximum IF Unit TIF signal transfer to the transmit mixer. The step also does not mention this but that is what T1 on the RF Unit is for, maximum TIF signal transfer to the transmit mixer.
>
> The step further states to adjust the "DRIVER" coil for maximum "ALC" indication. This is done for each band but the adjustment for each band driver coil is performed in a specific sequence (Fig 2.3 COIL PACK adjustments). This adjustment provides for maximum signal transfer (resonates the driver tube's PLATE circuit on the specific band) from the driver tube through the COIL PACK "DRV" terminal to the FINAL UNIT "DRV" terminal. The DRIVER coil pack adjustment serves 2 purposes
>

> One weak final tube out of two can easily exhibit a hotter glass envelope than the other, especially in your case. There is no way to determine which one is weaker by simply monitoring the IP meter display in transmit. The final amplifier operates in parallel and the IP meter current level is a combination of final tube screen and plate currents. The IP meter indication is displaying the final tubes "cathode current" which is the "safer" method to display plate current. In the old days a meter was connected in "series" with the final amplifier's HV supply.

It's better to know why one does something than rather to simply "do it and look for this..". My comments are not meant to be disrespectful but rather to help one to understand what the adjustment does and why.

> > >
> > > The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

> > > >
> > > > I took out the S-2001A's and put in two 6146's ï¿½ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!

I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to see how the B models will do in the 820S.

way the HV meter switch setting with display HV is in transmit. In receive the Relay Unit
relay terminals disables all meter switch settings and the meter displays receive signal
strength, S Units, ONLY.
> > > > > >
> > > > > > A more accurate method of measuring the 820's HV is to measure the HV at the
Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful
when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where
the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do
this if you are tired, being disrupted or distracted, as you can easily receive a severe
electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800
terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least
1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise
you can easily burn out your meter!!!

> > > > > > It is possible the HV filter capacitors are quite leaky due to age and previous usage. If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.
> > > > > >
> > > > > > Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

> > > > > > >
> > > > > > > RF2 has 4 pins that can affect the driver and both final tube's bias voltage, pins 7 thru 10. If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!
> > > > > > >
> > > > > > > If you have a set of known good driver and final tubes then I recommend using them then test for power output. I also recommend checking and, if necessary, replace the 2 cathode resistors, R5 and R6 both 10 ohm 1 watt. If these increase in resistance, for example, the current flow through the final tubes will be "less".

From your statements above, it appears you are attempting to adjust the bias pot for an IP meter indication of 60ma in TUNE mode. If that's true, you are doing it wrong. The bias pot is adjusted in USB or LSB ONLY, never in TUNE or CW mode.

Do it this way;

1. Set MIC gain completely CCW. Don't worry about the CAR control setting.
2. Connect 820 to dummy load
3. Place MODE switch to USB or LSB
4. Set meter switch to IP
5. Flip the SEND switch UP which will key the transmitter
6. Note the IP meter scale reading. If the meter points higher or lower than 60ma, adjust the bias pot on the rear for a 60ma meter indication
7. Flip the SEND switch DOWN, unkeys the transmitter

Note:

The IP meter scale is the top scale on the meter.

That's all there is to setting the 820 bias pot. The only time you should have to change the bias pot setting is if you change final tubes and you repeat step "6" above and notice the IP meter indicating higher or lower than 60ma. Otherwise you should not touch the bias pot. If you replace the driver tube only, you do not have to worry about changing the bias pot setting. You can also change just the driver tube without changing the final tubes. Quite often people are misled into believing if they change the driver tube they also have to change the final tubes which is not true.

> load in the MFJ tuner or switched into my Heathkit Cantenna.

I don't know what you are trying to achieve or say by the statements above. The 820, like all other hybrids, will not produce RF output if there is no audio applied from the microphone and/or the MIC gain is set fully CCW. This is normal for all single sideband transmitters. You cannot tune the 820 up in USB or LSB mode. You must tune the transmitter

up in TUNE mode. While it's possible to tune the transmitter in CW mode, you must understand that in TUNE mode the final tube screen voltage is "lowered" in order to prevent damage to the final tubes by inexperienced operators that key the transmitter too long while adjusting the PLATE and LOAD controls. In CW mode the final amplifier screen voltage is switched back to normal which, if the transmitter is left keyed too long could lead to damage to the final tubes. This is discussed in the 820's operator's manual.

> TS-520's but I understand they are preferred for the TS-820.

There are people who say a lot of things. The key is not to "mix" 6146 or 6146A with 6146B or vice verse. This means do not use one 6146 or 6146A and the other a 6146B.

The original 6146, what I call the "Plain Jane 6146", is very scarce and in most cases you will not find them. If you find them they are typically worn out, weak, and not usable. The 6146A on the other hand is quite available. You can purchase them from the following link for $22 each:

http://www.vacuumtubes.net/?source=google&gclid=CMStvMybj6YCFddA2godTAqtZA

By the way I use this company for all my vacuum tube needs and have never had a problem or a bad tube from them.

You can use the 6146A or 6146B in the 820. You will have to neutralize the final amplifier regardless of the tube version you use. I have successfully used 6146As and 6146Bs in my 820 without any problems. This notion that the 520 hybrids require 6146A is unfounded. I have never read anything that specifically calls for 6146As in any of the hybrids. As I said above, do NOT, for any reason, mix a 6146A and a 6146B! Although the tubes appear to be the same except for maximum power output, they are different. I recommend you read Glen Zook, K9STH, "The 6146 Family of Tubes" document in the "files" section of this group.

Don't expect 120 watts from a pair of 6146As because they are not designed for that level of parallel RF output. The 6146Bs, on the other hand, are. But, you must understand that you can easily push the final tubes beyond their recommended "normal" power output by improperly adjusting the "LOAD" control! A number of operators tend to believe they can push their hybrids for 150 watts output. I can tell you those operators will be spending money for new finals quicker than they realize by pushing the final amplifier too hard. Not only will they be buying new finals but rebuilding the power supplies! Follow the operator's manual tune procedure and do not try to achieve a higher power output by improperly adjusting the LOAD control!

The Japanese Beam Power tube, S2001, is the same as a 6146A and the Japanese Beam Power tube, S2001A, is the same as a 6146B.

>
> I have not run the neutralization procedure yet. That is next,
> since the rig does not appear to be in danger of melting from too

You should check and if necessary, neutralize the final amplifier. Since you have been swapping final tubes I recommend you neutralize the final amplifier.

T5 on the IF Unit is an IF amplifier transformer, same as T6, except T5 has a secondary winding that T6 does not have, for the transmitter's 8mhz TIF signal.

INRAD's adjustment appears to be adjusting the CAR Unit signal so the low and high end audio frequencies provide the same output by switching between USB and LSB, called "Sideband Balancing". The USB signal should have the same signal level as the LSB signal has to produce the same RF output regardless of the sideband setting, USB or LSB.

The Mode switch is set to "CW" and the CAR control set to 12 o'clock in order to provide an RF carrier which is not possible in USB or LSB without applying audio to the speech amplifier. The step does not state whether to have a CW key plugged into the CW socket or not. I recommend removing any CW key from the CW socket as this will allow the SEND switch, when flipped "UP" to key the transmitter and produce output. The CW socket is a "Normally Closed" socket so a CW key is not required in the CW socket during this transmitter alignment step.
> >
> > The 820 is keyed and T10 is adjusted for maximum 8Mhz "TIF" signal appearing at the IF Unit's plug IF3 pin 2 "TIF" terminal. This alignment step does not mention this but that's is what the adjustment of T10 on the IF Unit is for. The "TIF" signal is then applied to the RF Unit plug RF1 pin 1 where the "TIF" signal is applied to RF Unit transmit mixer transformer T1. T1 is adjusted for maximum IF Unit TIF signal transfer to the transmit mixer. The step also does not mention this but that is what T1 on the RF Unit is for, maximum TIF signal transfer to the transmit mixer.
> >
> > The step further states to adjust the "DRIVER" coil for maximum "ALC" indication. This is done for each band but the adjustment for each band driver coil is performed in a specific sequence (Fig 2.3 COIL PACK adjustments). This adjustment provides for maximum signal transfer (resonates the driver tube's PLATE circuit on the specific band) from the

driver tube through the COIL PACK "DRV" terminal to the FINAL UNIT "DRV" terminal. The DRIVER coil pack adjustment serves 2 purposes

> >
> >
> >
> > One weak final tube out of two can easily exhibit a hotter glass envelope than the other, especially in your case. There is no way to determine which one is weaker by simply monitoring the IP meter display in transmit. The final amplifier operates in parallel and the IP meter current level is a combination of final tube screen and plate currents. The IP meter indication is displaying the final tubes "cathode current" which is the "safer" method to display plate current. In the old days a meter was connected in "series" with the final amplifier's HV supply.

It's better to know why one does something than rather to simply "do it and look for this..". My comments are not meant to be disrespectful but rather to help one to understand what the adjustment does and why.

> > > >
> > > > The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

> > > > >
> > > > > I took out the S-2001A's and put in two 6146's ï¿½ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!

I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to see how

the B models will do in the 820S.

only way the HV meter switch setting with display HV is in transmit. In receive the Relay
Unit relay terminals disables all meter switch settings and the meter displays receive
signal strength, S Units, ONLY.
> > > > > > >
> > > > > > > A more accurate method of measuring the 820's HV is to measure the HV at the
Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful
when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where
the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do
this if you are tired, being disrupted or distracted, as you can easily receive a severe
electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800
terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least
1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise
you can easily burn out your meter!!!

> > > > > > >
> > > > > > > > ---
> > > > > > >
> > > > > > > > It is possible the HV filter capacitors are quite leaky due to age and previous usage. If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.
> > > > > >
> > > > > > > Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

> > > > > > > >
> > > > > > > > RF2 has 4 pins that can affect the driver and both final tube's bias voltage, pins 7 thru 10. If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!
> > > > > > > >
> > > > > > > > If you have a set of known good driver and final tubes then I recommend using them then test for power output. I also recommend checking and, if necessary, replace the 2 cathode resistors, R5 and R6 both 10 ohm 1 watt. If these increase in resistance, for example, the current flow through the final tubes will be "less".

"I recommend you spend a few dollars and buy an older ARRL handbook, a version in the mid 60s will do. Start at the beginning, learn about resistors, capacitors, inductors, how to computer resistance in series, parallel, series/parallel, and how current flows in a resistor. Learn basic ohms law, I = E/R, R = E/I, E = I x E, and Pin = I x E. You will use these basic ohms law formulas every time you troubleshoot simple or complex problems in any piece of electronic equipment. You can pick up the older ARRL handbooks on eBay."

Excellent advice. The ARRL handbooks from 1940's - 1960s set out the basic theory and practice of radio design, construction and operating very well. Ditto for the RSGB handbook. You may consider joining a QRP group, or the Yahoo group RegenRx. There are many experienced operators there.

Knowledge gained by doing is of a better quality than any other kind of knowledge.

Good success.

Les

-companies. The important thing is to ensure the chip is the same binary up counter with same or very similar voltage specifications and same pin designations. IC chips are almost all made in China, Taiwan, or other foreign countries and companies such as Toshiba and Texas Instruments simply have their name put on the chips. There are very few, if any, IC chips made in America.
>

I did check the data sheets prior to making my selection but I never knew that they didn't make chips in the States any more. That's kind of sad, but certainly not a surprise.
I figured that the quality standards are higher at Texas Instruments and that was my rational for the purchase. If I'm wrong, then I'm only out a couple of bucks and I'll live with it... and learn from it.
Thanks again, Mike.

29280. Re: Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-12 16:12:32 UTC
From: roberteleazer@rocketmail.com
Topic: 29230 Message: 29280

Mike:

First, let me say that I did the neutralization procedure on the 820S last night and I got it down to about 40 MV in CW mode and about 25 MV in SSB mode.

Now, as to what the rig is doing,

1. I set the idle current in Tune mode because in SSB mode I cannot get it below about 120ma with the current finals installed.
2. My 820S does produce considerable RF output with the mike control turned all the way CCW, and the mike even disconnected.
3. When I ran the INRAD alignment procedure (with the S-2001A's still installed) I found that I could adjust the SSB output up and down with the mike control, but could not get it below about 30W or so. I tried turning off the audio signal generator and disconnecting it to make sure that the signal generator output was not driving it and that did no good.

Based on what you say, I can only conclude that the carrier suppression of the rig is at least set incorrectly or at worst there is some kind of component failure. The only explanation for what I am seeing, based on what you say should be happening, is that some carrier is still leaking through in SSB mode. I have not touched that part of the set and I will have to get out the manual and get familiar with it. Signal reports from stations I have talked to do not indicate that I am throwing a carrier, but as I am sure you know, even with full AM it is easily possible to tune out the carrier.

Once again, thanks for your help.

Robert

>
> That's all there is to setting the 820 bias pot. The only time you should have to change the bias pot setting is if you change final tubes and you repeat step "6" above and notice the IP meter indicating higher or lower than 60ma. Otherwise you should not touch the bias pot. If you replace the driver tube only, you do not have to worry about changing the bias pot setting. You can also change just the driver tube without changing the final tubes. Quite often people are misled into believing if they change the driver tube they also have to change the final tubes which is not true.

>
>
> I don't know what you are trying to achieve or say by the statements above. The 820, like all other hybrids, will not produce RF output if there is no audio applied from the microphone and/or the MIC gain is set fully CCW. This is normal for all single sideband transmitters. You cannot tune the 820 up in USB or LSB mode. You must tune the transmitter up in TUNE mode. While it's possible to tune the transmitter in CW mode, you must understand that in TUNE mode the final tube screen voltage is "lowered" in order to prevent damage to the final tubes by inexperienced operators that key the transmitter too long while adjusting the PLATE and LOAD controls. In CW mode the final amplifier screen voltage is switched back to normal which, if the transmitter is left keyed too long could lead to damage to the final tubes. This is discussed in the 820's operator's manual.

>
> The original 6146, what I call the "Plain Jane 6146", is very scarce and in most cases you will not find them. If you find them they are typically worn out, weak, and not usable. The 6146A on the other hand is quite available. You can purchase them from the following link for $22 each:
>
> http://www.vacuumtubes.net/?source=google&gclid=CMStvMybj6YCFddA2godTAqtZA
>
> By the way I use this company for all my vacuum tube needs and have never had a problem or a bad tube from them.
>
> You can use the 6146A or 6146B in the 820. You will have to neutralize the final amplifier regardless of the tube version you use. I have successfully used 6146As and 6146Bs in my 820 without any problems. This notion that the 520 hybrids require 6146A is unfounded. I have never read anything that specifically calls for 6146As in any of the hybrids. As I said above, do NOT, for any reason, mix a 6146A and a 6146B! Although the tubes appear to be the same except for maximum power output, they are different. I recommend you read Glen Zook, K9STH, "The 6146 Family of Tubes" document in the "files" section of this group.
>
> Don't expect 120 watts from a pair of 6146As because they are not designed for that level of parallel RF output. The 6146Bs, on the other hand, are. But, you must understand that you can easily push the final tubes beyond their recommended "normal" power output by improperly adjusting the "LOAD" control! A number of operators tend to believe they can push their hybrids for 150 watts output. I can tell you those operators will be spending money for new finals quicker than they realize by pushing the final amplifier too hard. Not only will they be buying new finals but rebuilding the power supplies! Follow the operator's manual tune procedure and do not try to achieve a higher power output by improperly adjusting the LOAD control!

The USB signal should have the same signal level as the LSB signal has to produce the same RF output regardless of the sideband setting, USB or LSB.

applying audio to the speech amplifier. The step does not state whether to have a CW key plugged into the CW socket or not. I recommend removing any CW key from the CW socket as this will allow the SEND switch, when flipped "UP" to key the transmitter and produce output. The CW socket is a "Normally Closed" socket so a CW key is not required in the CW socket during this transmitter alignment step.
> > >
> > > The 820 is keyed and T10 is adjusted for maximum 8Mhz "TIF" signal appearing at the IF Unit's plug IF3 pin 2 "TIF" terminal. This alignment step does not mention this but that's is what the adjustment of T10 on the IF Unit is for. The "TIF" signal is then applied to the RF Unit plug RF1 pin 1 where the "TIF" signal is applied to RF Unit transmit mixer transformer T1. T1 is adjusted for maximum IF Unit TIF signal transfer to the transmit mixer. The step also does not mention this but that is what T1 on the RF Unit is for, maximum TIF signal transfer to the transmit mixer.
> > >
> > > The step further states to adjust the "DRIVER" coil for maximum "ALC" indication. This is done for each band but the adjustment for each band driver coil is performed in a specific sequence (Fig 2.3 COIL PACK adjustments). This adjustment provides for maximum signal transfer (resonates the driver tube's PLATE circuit on the specific band) from the driver tube through the COIL PACK "DRV" terminal to the FINAL UNIT "DRV" terminal. The DRIVER coil pack adjustment serves 2 purposes

> > >
> > >
> > >
> > > One weak final tube out of two can easily exhibit a hotter glass envelope than the other, especially in your case. There is no way to determine which one is weaker by simply monitoring the IP meter display in transmit. The final amplifier operates in parallel and the IP meter current level is a combination of final tube screen and plate currents. The IP meter indication is displaying the final tubes "cathode current" which is the "safer" method to display plate current. In the old days a meter was connected in "series" with the final amplifier's HV supply.

> > > > >
> > > > > The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

> > > > > >
> > > > > > I took out the S-2001A's and put in two 6146's ï¿½ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!

> > > > > > I think that I also will try the 6146B's that originally came with the rig. I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to see how the B models will do in the 820S.

> > > > > > >
> > > > > > > A more accurate method of measuring the 820's HV is to measure the HV at the

Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do this if you are tired, being disrupted or distracted, as you can easily receive a severe electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800 terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least 1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise you can easily burn out your meter!!!

> > > > > > > > > ----------
> > > > > > > >
> > > > > > > > > It is possible the HV filter capacitors are quite leaky due to age and previous usage. If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.
> > > > > > >
> > > > > > > > Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

> > > > > > > > >
> > > > > > > > > RF2 has 4 pins that can affect the driver and both final tube's bias voltage, pins 7 thru 10. If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!
> > > > > > > > >
> > > > > > > > > If you have a set of known good driver and final tubes then I recommend using them then test for power output. I also recommend checking and, if necessary, replace the 2 cathode resistors, R5 and R6 both 10 ohm 1 watt. If these increase in resistance, for example, the current flow through the final tubes will be "less".

29281. ts820 output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-12 16:13:46 UTC

Topic: 29281 Message: 29281

Mike and group;

I didn't reply to the other thread because it was too long already;
so I post a new msg about the ts820's output.
I use 6146w tubes in both of my kenwoods and so far not a problem.
6146w's will give you just a lower output, but the small amt doesn't
make a difference at the recv end.
Mike you have always given good advice and instructions on the forumn.
Over the years, I have learned a lot about Hybrids from this forumn and I have managed to repair a few of them(not for profit) and also restore
3 for myself(2 ts820s,1 ts520).
I repaired a ts820s that the previous owner changed the finals out because of low output. The radio had original s2001a's in it, so on the advice of someone he put a 6146 and a 6146b in and still had the same problem and more. I repaired the components that were burned out and he had the set of original S2001a's, I installed them to check and lo and behold they tested good, neutralized and some alignment and to this day he is using it every day.
Just thought I would share this story with the forumn.
don/w5dja

29282. Re: Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-12 17:21:43 UTC
From: w5rkl
Topic: 29230 Message: 29282

Robert.

From you response it appears the 820's carrier balance is out of alignment. This must be fixed first in order to set the final amplifier's no signal idling current.

When performing any test and/or adjustments in the 820 always connect the 820 to a dummy load. If you use an antenna to make the adjustments or perform test you will cause interference to other stations on the bands.

First, do not adjust the bias pot in TUNE or CW mode, regardless of the reason.

Second, turn to Page 49, paragraph 4.3 "Adjustment of carrier suppression". This step, when properly adjusted, will reduce the carrier which will allow you to set the final amplifier's no-signal bias pot adjust for 60ma.

Set the Mode switch to USB, turn the MIC gain completely CCW, set the meter switch to RF, and key the 820. Adjust VR5 on the IF Unit for a minimum indication on the meter. Adjust variable capacitor TC2 on the IF Unit board also for a minimum indication on the meter. Alternate between VR5 and TC2 for the lowest meter indication. Refer to figure 24 in the service manual on page 46 when performing the carrier suppression adjustments.

The above adjustments is simply to null the carrier in USB and LSB modes. This may not be the only problem your 820 has. As I stated above, the importance of the carrier suppression adjustment is to null the carrier so you can set the normal final amplifier idling current, in USB or LSB mode, to 60ma.

> 2. My 820S does produce considerable RF output with the mike control turned all the way CCW, and the mike even disconnected.
> 3. When I ran the INRAD alignment procedure (with the S-2001A's still installed) I found that I could adjust the SSB output up and down with the mike control, but could not get it below about 30W or so. I tried turning off the audio signal generator and disconnecting it to make sure that the signal generator output was not driving it and that did no good.

>
> Based on what you say, I can only conclude that the carrier suppression of the rig is at least set incorrectly or at worst there is some kind of component failure. The only explanation for what I am seeing, based on what you say should be happening, is that some carrier is still leaking through in SSB mode. I have not touched that part of the set and I will have to get out the manual and get familiar with it. Signal reports from stations I have talked to do not indicate that I am throwing a carrier, but as I am sure you know, even with full AM it is easily possible to tune out the carrier.

> > That's all there is to setting the 820 bias pot. The only time you should have to change the bias pot setting is if you change final tubes and you repeat step "6" above and notice the IP meter indicating higher or lower than 60ma. Otherwise you should not touch the bias pot. If you replace the driver tube only, you do not have to worry about changing the bias pot setting. You can also change just the driver tube without changing the final tubes. Quite often people are misled into believing if they change the driver tube they also have to change the final tubes which is not true.

> >
> > I don't know what you are trying to achieve or say by the statements above. The 820, like all other hybrids, will not produce RF output if there is no audio applied from the microphone and/or the MIC gain is set fully CCW. This is normal for all single sideband transmitters. You cannot tune the 820 up in USB or LSB mode. You must tune the transmitter up in TUNE mode. While it's possible to tune the transmitter in CW mode, you must understand that in TUNE mode the final tube screen voltage is "lowered" in order to prevent damage to the final tubes by inexperienced operators that key the transmitter too long while adjusting the PLATE and LOAD controls. In CW mode the final amplifier screen voltage is switched back to normal which, if the transmitter is left keyed too long could lead to damage to the final tubes. This is discussed in the 820's operator's manual.

> > http://www.vacuumtubes.net/?source=google&gclid=CMStvMybj6YCFddA2godTAqtZA
> >
> > By the way I use this company for all my vacuum tube needs and have never had a problem or a bad tube from them.
> >
> > You can use the 6146A or 6146B in the 820. You will have to neutralize the final

amplifier regardless of the tube version you use. I have successfully used 6146As and 6146Bs in my 820 without any problems. This notion that the 520 hybrids require 6146A is unfounded. I have never read anything that specifically calls for 6146As in any of the hybrids. As I said above, do NOT, for any reason, mix a 6146A and a 6146B! Although the tubes appear to be the same except for maximum power output, they are different. I recommend you read Glen Zook, K9STH, "The 6146 Family of Tubes" document in the "files" section of this group.
> >
> > Don't expect 120 watts from a pair of 6146As because they are not designed for that level of parallel RF output. The 6146Bs, on the other hand, are. But, you must understand that you can easily push the final tubes beyond their recommended "normal" power output by improperly adjusting the "LOAD" control! A number of operators tend to believe they can push their hybrids for 150 watts output. I can tell you those operators will be spending money for new finals quicker than they realize by pushing the final amplifier too hard. Not only will they be buying new finals but rebuilding the power supplies! Follow the operator's manual tune procedure and do not try to achieve a higher power output by improperly adjusting the LOAD control!

> > > >
> > > > This step states to adjust "T10" on the IF Unit board. T10 on the IF Unit board is the "balance modulator" transformer. The Mode switch is set to "CW" and the CAR control set to 12 o'clock in order to provide an RF carrier which is not possible in USB or LSB without applying audio to the speech amplifier. The step does not state whether to have a CW key plugged into the CW socket or not. I recommend removing any CW key from the CW socket as this will allow the SEND switch, when flipped "UP" to key the transmitter and produce output. The CW socket is a "Normally Closed" socket so a CW key is not required in the CW socket during this transmitter alignment step.
> > > >
> > > > The 820 is keyed and T10 is adjusted for maximum 8Mhz "TIF" signal appearing at the IF Unit's plug IF3 pin 2 "TIF" terminal. This alignment step does not mention this but that's is what the adjustment of T10 on the IF Unit is for. The "TIF" signal is then applied to the RF Unit plug RF1 pin 1 where the "TIF" signal is applied to RF Unit transmit mixer transformer T1. T1 is adjusted for maximum IF Unit TIF signal transfer to the transmit mixer. The step also does not mention this but that is what T1 on the RF Unit is for, maximum TIF signal transfer to the transmit mixer.
> > > >
> > > > The step further states to adjust the "DRIVER" coil for maximum "ALC" indication. This is done for each band but the adjustment for each band driver coil is performed in a

specific sequence (Fig 2.3 COIL PACK adjustments). This adjustment provides for maximum signal transfer (resonates the driver tube's PLATE circuit on the specific band) from the driver tube through the COIL PACK "DRV" terminal to the FINAL UNIT "DRV" terminal. The DRIVER coil pack adjustment serves 2 purposes

> > > >
> > > >
> > > > One weak final tube out of two can easily exhibit a hotter glass envelope than the other, especially in your case. There is no way to determine which one is weaker by simply monitoring the IP meter display in transmit. The final amplifier operates in parallel and the IP meter current level is a combination of final tube screen and plate currents. The IP meter indication is displaying the final tubes "cathode current" which is the "safer" method to display plate current. In the old days a meter was connected in "series" with the final amplifier's HV supply.

It's better to know why one does something than rather to simply "do it and look for this..". My comments are not meant to be disrespectful but rather to help one to understand what the adjustment does and why.

> > > > > >
> > > > > > The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

> > > > > > > >
> > > > > > > > I took out the S-2001A's and put in two 6146's ï¿½ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!

I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to see how the B models will do in the 820S.

In receive the Relay Unit relay terminals disables all meter switch settings and the meter displays receive signal strength, S Units, ONLY.
> > > > > > > >
> > > > > > > > A more accurate method of measuring the 820's HV is to measure the HV at the Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do this if you are tired, being disrupted or distracted, as you can easily receive a severe electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800 terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least 1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise you can easily burn out your meter!!!

previous usage. If a previous operator abuses the 820 but running it at above normal power
output levels through improper LOAD control adjustments or other abusive behavior due to
inexperience, it's not uncommon for this to happen, this could result in higher current
demands being placed on the HV supply causing early failure in the power supply components.
> > > > > > > > >
> > > > > > > > > > Electrolytic capacitors do age which can lead to higher internal leakage
current. When this happens the HV power supply output suffers as the output voltage sages
lower than normal during normal operation. The only fix is to replace both HV filter
capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging
filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing
resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals.
Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on
pricing and ordering.

> > > > > > > > > >
> > > > > > > > > > RF2 has 4 pins that can affect the driver and both final tube's bias voltage, pins 7 thru 10. If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!
> > > > > > > > > >
> > > > > > > > > > If you have a set of known good driver and final tubes then I recommend using them then test for power output. I also recommend checking and, if necessary, replace the 2 cathode resistors, R5 and R6 both 10 ohm 1 watt. If these increase in resistance, for example, the current flow through the final tubes will be "less".

29283. Re: Sudden Decrease in TS-820S RF output

Mike:

Not that the "meter" they show in Fig 24 to read is an RF voltmeter hooked through a directional coupler.

While I have some of the makings of that setup, and figure I could use the take-off on my Heathkit Cantenna and my scope to read minimum RF voltage, I decided to just read the wattmettr in USB mode and see if that worked to measure the carrier in SSB. And it did. after adjusting VR5 and TC2 on the IF board I got output in USB and LSB with no audio input down as shown on the wattmeter down to almost nothing.

One of the other features of this fix is that not only does the MIC control work all the way up and down but the CAR control does too.

I will go ahead and run the INRAD procedure again to see what results I get. I'm curious, but I expect no real changes.

Now as for 6146 vs. 6146B's vs. S-2001A's, I am curious about other people's recommendations and experiences. NOS and what appear to be good used 6146 and 6146A are very available; I just bought four tested good 6146 for less than $20.00. And you will recall that the two 6146 I tried out in the 820S were real screamers when it came to RF output. There are some definite opinions out there in the Internet and I do not know who to believe but I will do a separate post on that.

Thanks!

Robert

>
> First, do not adjust the bias pot in TUNE or CW mode, regardless of the reason.
>
> Second, turn to Page 49, paragraph 4.3 "Adjustment of carrier suppression". This step, when properly adjusted, will reduce the carrier which will allow you to set the final amplifier's no-signal bias pot adjust for 60ma.
>
> Set the Mode switch to USB, turn the MIC gain completely CCW, set the meter switch to RF, and key the 820. Adjust VR5 on the IF Unit for a minimum indication on the meter. Adjust

variable capacitor TC2 on the IF Unit board also for a minimum indication on the meter. Alternate between VR5 and TC2 for the lowest meter indication. Refer to figure 24 in the service manual on page 46 when performing the carrier suppression adjustments.
>
> The above adjustments is simply to null the carrier in USB and LSB modes. This may not be the only problem your 820 has. As I stated above, the importance of the carrier suppression adjustment is to null the carrier so you can set the normal final amplifier idling current, in USB or LSB mode, to 60ma.

> > 3. When I ran the INRAD alignment procedure (with the S-2001A's still installed) I found that I could adjust the SSB output up and down with the mike control, but could not get it below about 30W or so. I tried turning off the audio signal generator and disconnecting it to make sure that the signal generator output was not driving it and that did no good.
> >
> > Based on what you say, I can only conclude that the carrier suppression of the rig is at least set incorrectly or at worst there is some kind of component failure. The only explanation for what I am seeing, based on what you say should be happening, is that some carrier is still leaking through in SSB mode. I have not touched that part of the set and I will have to get out the manual and get familiar with it. Signal reports from stations I have talked to do not indicate that I am throwing a carrier, but as I am sure you know, even with full AM it is easily possible to tune out the carrier.

> > >
> > > That's all there is to setting the 820 bias pot. The only time you should have to change the bias pot setting is if you change final tubes and you repeat step "6" above and notice the IP meter indicating higher or lower than 60ma. Otherwise you should not touch the bias pot. If you replace the driver tube only, you do not have to worry about changing the bias pot setting. You can also change just the driver tube without changing the final tubes. Quite often people are misled into believing if they change the driver tube they also have to change the final tubes which is not true.

> > >
> > >
> > > I don't know what you are trying to achieve or say by the statements above. The 820, like all other hybrids, will not produce RF output if there is no audio applied from the microphone and/or the MIC gain is set fully CCW. This is normal for all single sideband transmitters. You cannot tune the 820 up in USB or LSB mode. You must tune the transmitter

up in TUNE mode. While it's possible to tune the transmitter in CW mode, you must understand that in TUNE mode the final tube screen voltage is "lowered" in order to prevent damage to the final tubes by inexperienced operators that key the transmitter too long while adjusting the PLATE and LOAD controls. In CW mode the final amplifier screen voltage is switched back to normal which, if the transmitter is left keyed too long could lead to damage to the final tubes. This is discussed in the 820's operator's manual.

> > >
> > > The original 6146, what I call the "Plain Jane 6146", is very scarce and in most cases you will not find them. If you find them they are typically worn out, weak, and not usable. The 6146A on the other hand is quite available. You can purchase them from the following link for $22 each:
> > >
> > > http://www.vacuumtubes.net/?source=google&gclid=CMStvMybj6YCFddA2godTAqtZA
> > >
> > > By the way I use this company for all my vacuum tube needs and have never had a problem or a bad tube from them.
> > >
> > > You can use the 6146A or 6146B in the 820. You will have to neutralize the final amplifier regardless of the tube version you use. I have successfully used 6146As and 6146Bs in my 820 without any problems. This notion that the 520 hybrids require 6146A is unfounded. I have never read anything that specifically calls for 6146As in any of the hybrids. As I said above, do NOT, for any reason, mix a 6146A and a 6146B! Although the tubes appear to be the same except for maximum power output, they are different. I recommend you read Glen Zook, K9STH, "The 6146 Family of Tubes" document in the "files" section of this group.
> > >
> > > Don't expect 120 watts from a pair of 6146As because they are not designed for that level of parallel RF output. The 6146Bs, on the other hand, are. But, you must understand that you can easily push the final tubes beyond their recommended "normal" power output by improperly adjusting the "LOAD" control! A number of operators tend to believe they can push their hybrids for 150 watts output. I can tell you those operators will be spending money for new finals quicker than they realize by pushing the final amplifier too hard. Not only will they be buying new finals but rebuilding the power supplies! Follow the operator's manual tune procedure and do not try to achieve a higher power output by improperly adjusting the LOAD control!

> > > > > >
> > > > > > This step states to adjust "T10" on the IF Unit board. T10 on the IF Unit board is the "balance modulator" transformer. The Mode switch is set to "CW" and the CAR control set to 12 o'clock in order to provide an RF carrier which is not possible in USB or LSB without applying audio to the speech amplifier. The step does not state whether to have a CW key plugged into the CW socket or not. I recommend removing any CW key from the CW socket as this will allow the SEND switch, when flipped "UP" to key the transmitter and produce output. The CW socket is a "Normally Closed" socket so a CW key is not required in the CW socket during this transmitter alignment step.
> > > > > >
> > > > > > The 820 is keyed and T10 is adjusted for maximum 8Mhz "TIF" signal appearing at the IF Unit's plug IF3 pin 2 "TIF" terminal. This alignment step does not mention this but that's is what the adjustment of T10 on the IF Unit is for. The "TIF" signal is then applied to the RF Unit plug RF1 pin 1 where the "TIF" signal is applied to RF Unit transmit mixer transformer T1. T1 is adjusted for maximum IF Unit TIF signal transfer to the transmit mixer. The step also does not mention this but that is what T1 on the RF Unit is for, maximum TIF signal transfer to the transmit mixer.
> > > > > >
> > > > > > The step further states to adjust the "DRIVER" coil for maximum "ALC" indication. This is done for each band but the adjustment for each band driver coil is performed in a specific sequence (Fig 2.3 COIL PACK adjustments). This adjustment provides for maximum signal transfer (resonates the driver tube's PLATE circuit on the specific band) from the driver tube through the COIL PACK "DRV" terminal to the FINAL UNIT "DRV" terminal. The DRIVER coil pack adjustment serves 2 purposes

> > > > > >
> > > > > > One weak final tube out of two can easily exhibit a hotter glass envelope than the other, especially in your case. There is no way to determine which one is weaker by simply monitoring the IP meter display in transmit. The final amplifier operates in parallel and the IP meter current level is a combination of final tube screen and plate currents. The IP meter indication is displaying the final tubes "cathode current" which is the "safer" method to display plate current. In the old days a meter was connected in "series" with the final amplifier's HV supply.

> > > > > > > > I would not operate the 820 with an RF output of more than 110 watts as that can easily over stress the power supplies and shorten the life of the final tubes.
> > > > > > > > >
> > > > > > > > The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

> > > > > > > >
> > > > > > > > I took out the S-2001A's and put in two 6146's ï¿½ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!

I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to see how the B models will do in the 820S.

> > > > > > > > > >
> > > > > > > > > > > A more accurate method of measuring the 820's HV is to measure the HV at the Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very careful when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this is where the final amplifier HV supply output feeds the final amplifier tubes! Do not attempt to do this if you are tired, being disrupted or distracted, as you can easily receive a severe electrical shock which can easily kill you!!! If you use a DVM to measure the HV at the 800 terminal on the Rectifier Unit, make sure the meter is capacitor of measuring at least 1,000 volts DC and the meter's voltage level switch is set to 1000VDC or higher otherwise you can easily burn out your meter!!!

If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.

> > > > > > > > >
> > > > > > > > > > Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

driver board, that can cause the fuse to blow is RF2.
> > > > > > > > > > >
> > > > > > > > > > > > RF2 has 4 pins that can affect the driver and both final tube's bias voltage, pins 7 thru 10. If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!
> > > > > > > > > > >
> > > > > > > > > > > > If you have a set of known good driver and final tubes then I recommend using them then test for power output. I also recommend checking and, if necessary, replace the 2 cathode resistors, R5 and R6 both 10 ohm 1 watt. If these increase in resistance, for example, the current flow through the final tubes will be "less".

Don:

Thank you this info.

I have read on the Internet that you should never ever use 6146B's in a TS-520. I have also read that you should not use 6146 or 6146A's. I got a set of 6146B's in the TS-820S that I have been working on for over a year, yanked them and put in some used S-2001A's. When I finally got the rig working I found that basic model 6146's worked great in terms of power output but that the original 6146B's that came with the rig work great too.

I understand about not mixing tubes; that makes sense, but I wonder what other people really are experiencing with the other models of the tube.

Regards,

Robert

There are major inter-electrode capacitance differences between the 6146/6146A and the 6146B. The B model has 10 watts more plate dissipation which makes the plate much larger hence the different capacitance. Don't know what restriction if any exists for the Kenwood hybrids using various flavors of the 6146 tube though. Collins had issues in their S-line and KWM2 when the 6146B came out, so they redesigned the neutralizing circuit and issued a service bulletin.

FWIW,

Greg
KG6YV

Greg:

Yes, I have read that. The famous Ken of Kenwood hybrids repair fame says you may have trouble neutralizing tubes other than the 6146B in the Kenwoods. One thing I did notice is that when I originally installed some 6146's in my TS-820 I was able to "neutralize" the finals right down to the point there was no output at all, even with the SG Switch on. With the 6146B's that was not a problem; I was able to get it down to only maybe 40MV in CW mode before turning the cap any more made it go back up again. So perhaps the earlier tubes are subject to "over-neutalization"?

In my TS-520 I have the S-2001A's that came installed and I have not even checked neutarlization with those. Probably would be interesting to do.

But in any case, my short period of trying out 6146's in my newly repaired and realigned TS-820S did not reveal any huge problems and provided plenty of RF output, although I never got to the neutralization step before swapping them out for 6146B's.

Thanks!

Robet

According to past experiences, the S2001's can be replaced with an 8298A, 6146B, and 6146W made after 1974 (any earlier 6146W tubes will be based on the 6146A tubes), the 8298A tube is a commercial release of the 6146B. The 6146B and it's variants lend themselves nicely to HF/VHF communications, while the 6146 and the 6146A were only useful as an HF tube since they would oscillate uncontrollably in VHF applications above 40mhz.

Much of this info was gleaned from the intraweb, but I have tested all of these tubes in both VHF and HF applications and verified that this information, in particular, is true.

I have also learned that a 6146B may not be replaced with an "A", 6146, or early "W" suffixed tube due to capacitance and oscillation issues, but any of the aforementioned could be replaced by thier successor with a slightly reduced power output.

As always, make sure the tubes are neutralized, and I personally like to keep a wattmeter inline to see if the tubes are doing what they should, and maintain thier output over time, also, when replacing tubes, especially during substitution, monitor plate current to make sure that the tubes aren't going into harmonic/parasitic oscillation, which could also be evidenced by looking at the tubes while keyed, they will glow orange almost immediately after keying the transmitter, and the plate current will go off the charts...

Happy hamming, this is what it's all about guys.

73, ke7szc, Bill.

Subject: [TS-520_820_530_830] Re: ts820 output

Greg:

Yes, I have read that. The famous Ken of Kenwood hybrids repair fame says you may have trouble neutralizing tubes other than the 6146B in the Kenwoods. One thing I did notice is that when I originally installed some 6146's in my TS-820 I was able to "neutralize" the finals right down to the point there was no output at all, even with the SG Switch on. With the 6146B's that was not a problem; I was able to get it down to only maybe 40MV in CW mode before turning the cap any more made it go back up again. So perhaps the earlier tubes are subject to "over-neutalization"?

In my TS-520 I have the S-2001A's that came installed and I have not even checked neutarlization with those. Probably would be interesting to do.

But in any case, my short period of trying out 6146's in my newly repaired and realigned TS-820S did not reveal any huge problems and provided plenty of RF output, although I never got to the neutralization step before swapping them out for 6146B's.

Thanks!

Robet

29288. Re: Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-13 16:52:23 UTC
From: w5rkl
Topic: 29230 Message: 29288

Robert,

While some of the following technical data refers to the Heathkit HW-101 5 band transceiver, the information provided is relative to this discussion.

Heathkit's HW-101 service bulletin, HW-101-18 dated Jan 20 1978, regarding failure of the final amplifier's RF choke due to overheating, clearly stated that using 6146Bs "may" be the reason for the HW-101's final amplifier RF choke failure on 10 and 15 meters. Heathkit stated in that service bulletin to use only 6146As.

Heathkit HW-101 service bulletin, HW-101-39 dated Nov 20 1978, stated that there were some 6146 tubes incorrectly marked with both 6146A and 6146B labels. Again, Heathkit stated to always use 6146A in the final amplifier.

However, Heathkit's HW-101 service bulletin, HW-101-49 dated May 15, 1979, stated that 6146As, at the time, were no longer available and that 6146B would be used as replacements. Furthermore, Heathkit clearly stated that "GE" brand 6146Bs had been tested and no difficulties were encountered neutralizing the final amplifier and no further failures in the final amplifier's RF choke were noted/found.

Does this mean that not all brands of 6146 tubes are the same? Honestly, I cannot answer that question with a definitive answer since I have not conducted a thorough test using all brands of 6146 tubes nor do I intend on doing so now or in the future. I can only provide you with the above factual information pertaining to the use of different versions of 6146s in the Heathkit HW-101.

There are more and more Chinese manufactured tubes being sold on the market today. I have read statements from owners and operators who have used Chinese manufactured tubes such as low power 6146 and high power 811A, 572B, and 3-500Z tubes where early tube failures have occurred. Reasons for failure have been stated to be the "quality" of the tubes as compared to the British Taylor and American Eimac brand of tubes. There are Russian manufactured tubes that appear to be of much higher quality. However, the only Russian tube I have ever used is a pair of El-34 Pentode tubes used in an AM modulator and they appeared to work rather well in the circuit they were used in, an AM transmitter's modulator. Does this means Russian tubes are better? No it does not. It simply means the EL-34 tubes I used which was Russian made "appeared" to work well, nothing more. Assuming the Russian made EL-34 tube didn't fail without thorough testing, which I did not do, is just that, an assumption, nothing more.

There have been statements made that the differences in inter-electrode capacitance between the 6146A and 6146B is because of the difference in anode density. I mean on disrespect but I have not read nor am I convinced that the difference in anode density between the 6146A and 6146B is what causes the differences in inter-electrode capacitance between the 6146A and 6146B. We can assume it is but without thorough test results, it is just that, an assumption.

I have also read where operators have installed 6146A or 6146Bs, depending on the final amplifier in question, and tune up on 80 or 40 meters achieving full output, therefore the specific version of tube they used is safe to use. That type of testing is inconclusive since the test was not conducted on 15 and 10 meters which is where most, if not all, instability relating to 6146A and 6146B versions of tubes occurs.

If you are unsure which version to use, as your "I do not know who to believe" statement says, then may I recommend you perform you own thorough tests using both versions of 6146 tubes to see for yourself which version of 6146 tubes is more or less stable in your 820. As Glen (K0STH) stated, and I agree, monitoring of the final amplifier neutralization over a period of hours and/or days is essential.

73s
Mike

>
> Now as for 6146 vs. 6146B's vs. S-2001A's, I am curious about other people's recommendations and experiences. NOS and what appear to be good used 6146 and 6146A are very available; I just bought four tested good 6146 for less than $20.00. And you will recall that the two 6146 I tried out in the 820S were real screamers when it came to RF output. There are some definite opinions out there in the Internet and I do not know who to believe but I will do a separate post on that.

> >
> > Set the Mode switch to USB, turn the MIC gain completely CCW, set the meter switch to RF, and key the 820. Adjust VR5 on the IF Unit for a minimum indication on the meter. Adjust variable capacitor TC2 on the IF Unit board also for a minimum indication on the meter. Alternate between VR5 and TC2 for the lowest meter indication. Refer to figure 24 in the service manual on page 46 when performing the carrier suppression adjustments.
> >
> > The above adjustments is simply to null the carrier in USB and LSB modes. This may not be the only problem your 820 has. As I stated above, the importance of the carrier suppression adjustment is to null the carrier so you can set the normal final amplifier idling current, in USB or LSB mode, to 60ma.

> > > 3. When I ran the INRAD alignment procedure (with the S-2001A's still installed) I found that I could adjust the SSB output up and down with the mike control, but could not get it below about 30W or so. I tried turning off the audio signal generator and disconnecting it to make sure that the signal generator output was not driving it and that did no good.
> > >
> > > Based on what you say, I can only conclude that the carrier suppression of the rig is at least set incorrectly or at worst there is some kind of component failure. The only explanation for what I am seeing, based on what you say should be happening, is that some carrier is still leaking through in SSB mode. I have not touched that part of the set and I

will have to get out the manual and get familiar with it. Signal reports from stations I have talked to do not indicate that I am throwing a carrier, but as I am sure you know, even with full AM it is easily possible to tune out the carrier.

> > > >
> > > > That's all there is to setting the 820 bias pot. The only time you should have to change the bias pot setting is if you change final tubes and you repeat step "6" above and notice the IP meter indicating higher or lower than 60ma. Otherwise you should not touch the bias pot. If you replace the driver tube only, you do not have to worry about changing the bias pot setting. You can also change just the driver tube without changing the final

tubes. Quite often people are misled into believing if they change the driver tube they also have to change the final tubes which is not true.

> > > > >
> > > > >
> > > > > I don't know what you are trying to achieve or say by the statements above. The 820, like all other hybrids, will not produce RF output if there is no audio applied from the microphone and/or the MIC gain is set fully CCW. This is normal for all single sideband transmitters. You cannot tune the 820 up in USB or LSB mode. You must tune the transmitter up in TUNE mode. While it's possible to tune the transmitter in CW mode, you must understand that in TUNE mode the final tube screen voltage is "lowered" in order to prevent damage to the final tubes by inexperienced operators that key the transmitter too long while adjusting the PLATE and LOAD controls. In CW mode the final amplifier screen voltage is switched back to normal which, if the transmitter is left keyed too long could lead to damage to the final tubes. This is discussed in the 820's operator's manual.

> > > > > By the way I use this company for all my vacuum tube needs and have never had a problem or a bad tube from them.
> > > > >
> > > > > You can use the 6146A or 6146B in the 820. You will have to neutralize the final amplifier regardless of the tube version you use. I have successfully used 6146As and 6146Bs in my 820 without any problems. This notion that the 520 hybrids require 6146A is unfounded. I have never read anything that specifically calls for 6146As in any of the hybrids. As I said above, do NOT, for any reason, mix a 6146A and a 6146B! Although the tubes appear to be the same except for maximum power output, they are different. I recommend you read Glen Zook, K9STH, "The 6146 Family of Tubes" document in the "files"

section of this group.
> > > >
> > > > Don't expect 120 watts from a pair of 6146As because they are not designed for that level of parallel RF output. The 6146Bs, on the other hand, are. But, you must understand that you can easily push the final tubes beyond their recommended "normal" power output by improperly adjusting the "LOAD" control! A number of operators tend to believe they can push their hybrids for 150 watts output. I can tell you those operators will be spending money for new finals quicker than they realize by pushing the final amplifier too hard. Not only will they be buying new finals but rebuilding the power supplies! Follow the operator's manual tune procedure and do not try to achieve a higher power output by improperly adjusting the LOAD control!

> > > > > >
> > > > > > This step states to adjust "T10" on the IF Unit board. T10 on the IF Unit board
is the "balance modulator" transformer. The Mode switch is set to "CW" and the CAR control
set to 12 o'clock in order to provide an RF carrier which is not possible in USB or LSB
without applying audio to the speech amplifier. The step does not state whether to have a
CW key plugged into the CW socket or not. I recommend removing any CW key from the CW
socket as this will allow the SEND switch, when flipped "UP" to key the transmitter and
produce output. The CW socket is a "Normally Closed" socket so a CW key is not required in
the CW socket during this transmitter alignment step.
> > > > > >
> > > > > > The 820 is keyed and T10 is adjusted for maximum 8Mhz "TIF" signal appearing at
the IF Unit's plug IF3 pin 2 "TIF" terminal. This alignment step does not mention this but
that's is what the adjustment of T10 on the IF Unit is for. The "TIF" signal is then
applied to the RF Unit plug RF1 pin 1 where the "TIF" signal is applied to RF Unit transmit
mixer transformer T1. T1 is adjusted for maximum IF Unit TIF signal transfer to the
transmit mixer. The step also does not mention this but that is what T1 on the RF Unit is
for, maximum TIF signal transfer to the transmit mixer.
> > > > > >
> > > > > > The step further states to adjust the "DRIVER" coil for maximum "ALC"
indication. This is done for each band but the adjustment for each band driver coil is
performed in a specific sequence (Fig 2.3 COIL PACK adjustments). This adjustment provides
for maximum signal transfer (resonates the driver tube's PLATE circuit on the specific
band) from the driver tube through the COIL PACK "DRV" terminal to the FINAL UNIT "DRV"
terminal. The DRIVER coil pack adjustment serves 2 purposes

> > > > > >
> > > > > > > One weak final tube out of two can easily exhibit a hotter glass envelope than the other, especially in your case. There is no way to determine which one is weaker by simply monitoring the IP meter display in transmit. The final amplifier operates in parallel and the IP meter current level is a combination of final tube screen and plate currents. The IP meter indication is displaying the final tubes "cathode current" which is the "safer" method to display plate current. In the old days a meter was connected in "series" with the final amplifier's HV supply.

> > > > > > > >
> > > > > > > > The HV at maximum output will sag but not excessively. A HV drop of 100VDC is not uncommon in a properly operating 820. The HV in my 820 is 825VDC in standby (receive) and approximately 745VDC at full output in CW mode. Some hybrid owners use higher value capacitors which can raise the HV. I use new 100ufd 500VDC HV filter capacitors, same as the designed HV filter supply. The "80/20" rules applies when working with capacitors, no more than 80% higher than the original value and no lower than 20% of the original value. I decided to stick with the original values, 100ufd at 500VDC capacitors.

> > > > > > > > >
> > > > > > > > > I took out the S-2001A's and put in two 6146's ï¿½ basic models, no A or B. The difference is dramatic. With a few short transmits into the dummy load I get about 250 ma of Ip current with the plate dipped and 90W indicated on the power meter in USB on 20M. On CW I get well over 100W indicated with about 750V on HV at that point. Obviously the high voltage power supply is putting out well. I have never seen RF output like this with this radio. It's too high!

I assumed they were not working properly at that time, but given the condition of the radio at that point it is not surprising. In my HW-100 they were a bit low on output but worked; of couwse that rig needs some work too so it is not a good example. I am curious to

see how the B models will do in the 820S.

> > > > > > > > > > > When you measure the HV is the 820 keyed with the SG switch ON and OFF?
The only way the HV meter switch setting with display HV is in transmit. In receive the
Relay Unit relay terminals disables all meter switch settings and the meter displays
receive signal strength, S Units, ONLY.
> > > > > > > > > >
> > > > > > > > > > > A more accurate method of measuring the 820's HV is to measure the HV
at the Rectifier Unit's "800" terminal with a DVM, whether in receive or transmit. Be very
careful when measuring the voltage at the Rectifier Unit's 800 terminal with a DVM as this
is where the final amplifier HV supply output feeds the final amplifier tubes! Do not
attempt to do this if you are tired, being disrupted or distracted, as you can easily
receive a severe electrical shock which can easily kill you!!! If you use a DVM to measure
the HV at the 800 terminal on the Rectifier Unit, make sure the meter is capacitor of
measuring at least 1,000 volts DC and the meter's voltage level switch is set to 1000VDC or
higher otherwise you can easily burn out your meter!!!

> > > > > > > > > > > > It is possible the HV filter capacitors are quite leaky due to age and previous usage. If a previous operator abuses the 820 but running it at above normal power output levels through improper LOAD control adjustments or other abusive behavior due to inexperience, it's not uncommon for this to happen, this could result in higher current demands being placed on the HV supply causing early failure in the power supply components.
> > > > > > > > > > >
> > > > > > > > > > > > Electrolytic capacitors do age which can lead to higher internal leakage current. When this happens the HV power supply output suffers as the output voltage sages lower than normal during normal operation. The only fix is to replace both HV filter capacitors. Do not attempt to "reform" the capacitors, that simply will not fix an aging filter capacitor. I also recommend replacing the two 470K 1/2 watt voltage equalizing resistors and the two .01ufd 2KV disc capacitors across the HV filter capacitor terminals. Ken, K4EAA, sells a HV rebuild kit. Go to his website, www.k4eaa.com for further details on pricing and ordering.

> > > > > > > > > >
> > > > > > > > > > RF2 has 4 pins that can affect the driver and both final tube's bias voltage, pins 7 thru 10. If the plug is situated so pins 7 thru 10 are not making contact with pins 7 thru 10 then the driver and both final tube's bias voltage will be "disconnected". This will result in the driver and both final tubes to conduct to "saturation" current levels which can easily lead to the fuse blowing. Depending on the condition of the driver and/or final tubes, this can lead to problems with the tubes which could easily lead to lower RF output power. In addition, this could lead to damage to the cathode resistors which also can lead to lower RF output. By the way, if the bias voltage is "disconnected" to the final tubes and the fuse does NOT blow, the plates of the final tubes will start turning "RED", even in "receive"!
> > > > > > > > > > >
> > > > > > > > > > > If you have a set of known good driver and final tubes then I recommend using them then test for power output. I also recommend checking and, if necessary, replace the 2 cathode resistors, R5 and R6 both 10 ohm 1 watt. If these increase in resistance, for example, the current flow through the final tubes will be "less".

Bill:

Well, that is all very interesting. The only reply I cna give is to quote Glen Zook, K9STH, who has a great deal of professional experience in the area:

"Replacing the 6146 / 6146A tubes with 6146B types often results in spurious emissions, parasitic oscillations, etc. This is due to the fact that there are different bias requirements, different inter-electrode capacitances, etc. of the 6146B versus the other two. It is often difficult to neutralize 6146B tubes when used in place of the 6146 / 6146A. If neutralization can be achieved, often it lasts for just a few minutes before the tube(s) goes into oscillation."

"If one insists on trying the 6146B tubes in place of the 6146 / 6146A types, the very first thing to do is to neutralize the final amplifier. If it will not neutralize, then the 6146B tubes should immediately be replaced with the older type tubes. If it does neutralize, then the neutralization should be "watched" for several hours (even days) of operation. If the neutralization changes, then the 6146B tubes again should be replaced with the 6146 / 6146A series. If the neutralization remains constant after several days, then use of the 6146B is fine in that particular transmitter."

- So I guess that both you and he say swapping 6146B's for the earlier versions is fine if it turns out fine. But it appears that he doubts very much that it will be fine.

Thanks!!

Robert

John:

I don't know where it was set then. That was with 6146's installed. I have since put in the 6146B's that came with the rig, set the carrier suppression, and neutalized the finals and all now seems to be the best it ever has been with this particular rig.

I can now go over 100W in CW with the CAR control and all the way up and down in power with the MIC control.

One thing I have noticed is that with the MFJ-949E antenna tuner there is a huge interaction between the loading control and the antenna tuner. It is possible to tune the rig up with the Load control in the one place, set for what looks like Max output on the 820S meter, and then get everything looking good and have very little RF output. Then you move the load cotrol to another spot and tune up and things are much better. I never noticed that with the MFJ-941D or the Cubic antennna tuner.

Thanks!

Robert

Installed the CW Filter and had NO ALC indication initally. A quick tweak of the CW Carrier crystal moved the OSC output into the center of the filter passband and all is well.

Rewired the unused FIX Channel switch to allow selecting either the original SSB or the new CW filter (Wide/Narrow) when in the CW Mode. Wonderful upgrade to this old workhorse.

Robert,

If the SWR between the 820 and the tuner is very low, as seen on the tuner's SWR meter, but very little power, if any, appears at the tuner's antenna connector then the tuner is absorbing the power.

A quick method to determine of the power is being absorbed in the tuner is to tune the tuners for minimum SWR between the radio and the tuner. Note the SWR reading. Unkey the transmitter then remove the antenna from the tuner. Key the radio and quickly note the SWR reading on the tuner's SWR meter. If the SWR remains low, with the antenna disconnected from the tuner, then the tuner is absorbing the power. This, of course, is assuming the tuner's band setting is set to the appropriate band.

I have only experienced this once or maybe twice in my 40 years as a ham using a tuner. This does not happen very often but when it does the above test method is a quick way to determine whether the tuner is absorbing the power or not. The above test, keying the transmitter with the antenna disconnected from the tuners output.

The above test does not include any wiring or component failures. Therefore, before you perform the above test I recommend you open up the tuner and check for broken wires, bad components, or shorted variable capacitors and/or damaged roller inductors. Some tuners have a roller inductor that causes a disk to move from one end of the inductor to the other by rotating the inductor from the front panel control.

Remember, a tuner simply changes the antenna load to a value suitable for the transmitter to work into. The SWR displayed on the tuners SWR meter is the SWR between the transceiver and the tuner's input. The SWR and/or impedance to the actual antenna does not change by the use of a tuner. The tuner's output adjustments simply provides as close of a match to the load the antenna is presenting to the tuner's output, nothing more.

73s
Mike

Loading the rig into a tuner that has not been adjusted properly can never work well.
 Tuning up with A random point on the loading control is NOT The way to do it. You should always start with a minimum (CCW) position on the loading control, dip the plate and advance the loading slowly while resetting the plate for minimum current unltil you reach your proper Ip reading.
 If I was using a tuner I would get it set up before running any power, as in tuning the PA for full power.
 Just a few watts out will be enough to pre-tune your random frequency
 antennas.
Since I grew up with tube rigs (several home made) I just am amazed very few newer hams get the art of load and dip ! :D

29294. value of a thread (was sudden decrease in output)

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

From: Leslie Smith
Topic: 29294 Message: 29294

Dear Group,

I followed the various postings in this thread with interest - from the effect of various types of closely related output valves (the 6146 vs 6146-A vs 6146-B ...) and the ability of any tube to operate correctly, including the ability to neutralize the different types. Then there was the inference of Heathkit's experience with these variants. Finally the thread moved to the effect of the load, and the proper procedure used to tune the final into a reactive load.

Together the various postings are quite informative. Every contribution was appreciated.

29295. Re: Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-14 02:33:33 UTC
From: roberteleazer@rocketmail.com
Topic: 29230 Message: 29295

John and Mike:

What I was trying to describe is this:

I will switch the antenna tuner into the dummy load, put the rig in "Tune" mode and adjust for max power and minimum Ip on the radio's meter and the antenna tuner's wattmeter.

Then I switch over to mode that will put out some power CW or SSB - still into the dummy load - and discover that my Load setting is not correct any more. In fact, I can find 820S load setting and an antenna tuner setting that look good in Tune but is exactly wrong in terms of real RF power output.

Then if I change the Load setting everything changes. I can end up chasing the settings on the radio and the anenna tuner around. Tweak the Load control and it will make big changes in the required Antenna Tuner settings. At that point it is best to start over at Tune mode.

It seems that with the MFJ-949E, unlike the other two antenna tuners I have tried, there are often two settings that will look good in Tune mode but will give radically different results in terms of power delivered to the dummy load. MFJ even says this is possible but with the other two tuners it did not seem to happen nearly as readily.

Thanks!

Robert

29296. Re: Sudden Decrease in TS-820S RF output

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-14 02:45:07 UTC
From: Ken
Topic: 29230 Message: 29296

It's apparent that some folks do not realize the Pi-Net output circuitry is in fact a "tuner" that matches the final tubes Plate impedance to the Load impedance and that adding another "tuner" after the Pi-Net only complicates things.

The external "tuner" is not needed in most cases. If the Pi-Network can't tune it, fix it.

>
> Then I switch over to mode that will put out some power CW or SSB - still into the dummy load - and discover that my Load setting is not correct any more. In fact, I can find 820S load setting and an antenna tuner setting that look good in Tune but is exactly wrong in terms of real RF power output.
>
> Then if I change the Load setting everything changes. I can end up chasing the settings on the radio and the anenna tuner around. Tweak the Load control and it will make big changes in the required Antenna Tuner settings. At that point it is best to start over at Tune mode.
>
> It seems that with the MFJ-949E, unlike the other two antenna tuners I have tried, there are often two settings that will look good in Tune mode but will give radically different results in terms of power delivered to the dummy load. MFJ even says this is possible but with the other two tuners it did not seem to happen nearly as readily.

BRAVO ! well stated.

When I moved to my present QTH I built all my homerew antennas to match 50 ohm coax feed and eliminate the need to mess with a tuner.

Subject: [TS-520_820_530_830] Re: Sudden Decrease in TS-820S RF output

It's apparent that some folks do not realize the Pi-Net output circuitry is in fact a "tuner" that matches the final tubes Plate impedance to the Load impedance and that adding another "tuner" after the Pi-Net only complicates things.

The external "tuner" is not needed in most cases. If the Pi-Network can't tune it, fix it.

Good morning Robert,

Remove any CW key or CW keyer plug inserted in the 820s' rear CW socket.

Note the tuners has 3 knobs, one on the left, one in the middle, and one on the right. Since I don't recall what tuner you are using I will refer to the left knob as knob "A" and the right knob as knob "B". The center knob is typically the band switch knob which must be set to the appropriate band the 820 will be using.

Set knobs "A" and "B" so they point to 9 o'clock.

Set the center knob to the band the 820 will be operating on.

1. Connect the 820 to the dummy load. If the tuner has a built in dummy load set the tuners' switch to dummy load. Set tuners' SWR meter to read forward power, not SWR

2. Set Mode switch to TUNE

3. Set the 820 meter switch to ALC

4. Set the CAR control at 9 or 10 o'clock

5. Flip the SEND switch UP (keys the transmitter)

6. Adjust the DRIVE control for a peak meter indication. If the meter pegs full scale to the right, reduce the CAR control so the meter points at 12 o'clock.

7. Repeat step 6 for a peak meter indication

8. Set meter switch to IP

9. Adjust the PLATE control for maximum DIP in IP meter indication (reduction in IP current)

10. While watching the tuners' power output meter, adjust the LOAD control for a peak indication.

11. Return to the PLATE control and adjust for any further dip in IP current

12. Repeat steps 10 and 11 until there is no further dip in IP current and no further peak in RF output on the tuner's power output meter.

13. Flip the SEND switch DOWN (unkeys the transmitter). Let the 820 sit for a minute or two so the final amplifier tubes can cool down.

14. Set the Mode switch to CW

15. Flip the SEND switch UP (keys the transmitter)

16. Repeat steps 10 and 11. If no further dip in IP current and no further peak of RF output is noted flip the SEND switch down (unkeys the transmitter).

17. Set the tuners' front panel control from dummy load to the tuners' antenna setting. This connects the 820 to the tuners' input.

18. Set the 820's CAR control fully CCW

19. Set the tuners' meter switch to SWR

20. Flip the SEND switch UP (keys the transmitter)

21. Rotate the CAR control to the 820s' IP meter indicates approximately 150ma. This level keeps the final current lower than the normal 225ma at full output

22. Adjust knob "A" for a reduction in the tuners' SWR meter

23. Adjust knob "B" for a further reduction in the tuners' SWR meter

24. Alternate between steps 22 and 23 until you achieve the lowest SWR reading possible. This may not be a perfect 1:1 but it should be quite low.

25. Rotate the 820s' CAR control for an IP meter indication of 225ma, set the tuners' meter to display power output. The tuners' meter should display full output, approximately 100 to 110 watts.

26. Flip the SEND switch DOWN (unkeys the transmitter).

Perform the above steps "quickly". If necessary, unkey the transmitter between steps. The key is not to keep the 820 keyed at full output for more than a few seconds.

I agree, the PI Network does operate similar to a tuner. The transmitters' PI Networks' job is to transform the final amplifier's output high impedance down to a much lower impedance, typically 50 ohms. The impedance range of the 820s' PI Network has a limited impedance range, between approximately 30 ohms to 100 ohms or so.

An antenna tuner performs a similar function as the PI Network does. The tuner transformers a high antenna system impedance to a low impedance to match as closely as possible to the transmitters' output impedance.

Not all antennas require a tuner. If the feed line is coax, the antenna is built for a certain band, and the antenna is trimmed for the lowest SWR, an antenna tuner is not needed.

A G5RV antenna is considered to be an "all band" antenna. However, not all G5RV antennas will work on all HF ham bands without changing the feed line configuration. For example, a 102 foot long G5RV will not operate on 160 meters without changes made. Regardless of the length of the G5RV antenna used, a tuner is required for maximum efficiency and power transfer (lowest SWR) from the transmitter to the antenna.

The ARRL handbook and other documents discuss the various types of antenna and feed lines along with what tuners to use etc. I recommend reading them for a more detailed description on this subject.

Ken and John,

While this is true for the most part, there are antennas and feed lines arrangements that do require a tuner.

An inverted L, a long wire, G5RV, or an open wire fed antennas require an antenna tuner.

Modern and most vintage transmitters and transceivers along with linear amplifiers have unbalanced coax outputs. Unbalanced coax outputs are not directly compatible with balanced or end fed antennas. Therefore some form of matching network, a tuner for example, is required for maximum power transfer from the transmitter to the antenna for maximum efficiency.

As I stated in my previous response, not all antennas require a tuner.

Mike,
My SteppIR doesn't require a Tuner :-) It tunes itself Hi Hi...
But you are correct, My Verticals both do If I move too far from the
Band centers, especially on 80 and 160
Hope all is well.
73,
Gordon

Mike:

The procedure you describe is just exactly what I do to tune up, with two exceptions:

1. Before switching to the dummy load I switch the tuner to the antenna, select the coil that provides the best received signal, and adjust the "Antenna" and "Transmitter" variable caps to get the best signal. Not only should this be closer to the settings required for transmit (similar to what it is for the Drive control on the TS-820S) but it would be pointless to tune up without good reception.

2. After I have switched to the dummy load, I adjust the Transmitter and Antenna caps on the tuner while transmitting as reqired to maximize indicated RF power and minimize SWR. But you should never, ever switch coils on the antenna tuner while transmitting. Of course I do not ever do this myself but somebody at my station must because I have a small collection of burned out antenna tuner rotary switches. I have yet to apprehend the miscreant responsible. A rotary coil tuner may be a required purchase in the future to foil this terrorist. In fact, I bought a rotary tuner a couple of months back but the guy stiffed me and I never got it.

Thanks again for your insights.

Robert

Gordon ,

I thought the SteppIR required paper money for a tuner . <grin>

But I love it for contesting .

Hope you are doing well .

Hi Gordon,

Antennas for 80 and 160 quite often have a narrow band width. I have a 5BTV vertical that requires no tuner on all bands. Having said that, if I moved more than about 25Khz either side of the tuned vertical frequency on 80 meters the efficiency and SWR with the vertical goes to pot.

For the heck of it last year when 6 was open, I tried using the 5BTV vertical on 6 meters. I removed the 80 meter resonator so the vertical is now a 4BTV. Surprisingly I was able to work quite a few stations on 6. The SWR was below 2:1. I credit the low SWR to the 100 foot long coax run from the shack to the remote antenna switch. The vertical is not designed to operate on 6 but it was fun working stations using it.

I have a shortened 80 meter dipole that when erected as high as I can get it, allows me to work almost everyone I can hear with a low SWR without a tuner. However, the shortened 80 meter dipole has a narrow bandwidth either side of the resonant frequency. I use to check into the local area AM group a few years back, I no longer operate AM, and the dipole worked very well.

I have never tried a SteppIR but I have tried and currently use a G5RV through a Drake MN-2000 tuner. It does a very good job even though I am only able to get it up 30 feet.

I'm not a contester or DX Chaser, or awards chaser. I ragchew on CW and sometimes, when I'm in the mood, operate sideband.

I'm doing well. The weather is warming up after a week of below freezing temperatures. We had 2 inches of snow fall last week but most of it is gone now. There is still some snow in the shaded areas.

Hi Charlie,
Yes it does hi hi.
I love mine for contesting as well. I'm thinking of adding the 30/40
add-on this summer.
I am doing Great. Thanks for asking.
Feel better then I have in 15 years now that I have a new lung.
I hope all is well with you alos.

Hi Mike,
I find the same thing with my 80 and 160 antennas. Move very far
from center and the SWR goes up quickly.
I had a Long wire a few years ago for 160, it needed a tuner for sure,
but it worked very well for me.
I have used my Butternut HF6V on 6 meters but it doesn't work as well as
my SteppIR.
I work a lot of CW and SSB as well as some PSK and RTTY. I try to be
versatile hi hi
Our temps are rising. We are supposed to be close to 80 for the
next few days. I Love it.
Great weather to do Antenna work.

I was going to go out and do some Antenna work today, but it is
literally too Hot out there right now.
Patio Thermometer says 80 at this Moment.

You guys can keep the Cold !!

HI Gordon ,
Please send some of that heat my way. It has been colder than flint here in MO.
Good to see you feeling better. Thanks again for all your help the old 830 is
working like a charm now!
Take care god bless
73s
George

I was going to go out and do some Antenna work today, but it is
literally too Hot out there right now.
Patio Thermometer says 80 at this Moment.

You guys can keep the Cold !!

17 and dropping here... Won't see 80 degrees for at least 4, more likely 5 months...

I'm so envious, Gordon!!!

Gordon,

Yeah, too cold for me, too....

Thinking that Florida may be a better place to retire... When I was young (mid 60's) I can remember a bunch of us going up to Vermont to operate November Sweepstakes... Was a blast. It snowed ALL weekend. At the end, we cut the guys on the tower and just let it fall into the 3' feet of snow, loaded it up onto the roof of one of our cars and headed home with smiles on our faces and no issues with the cold weather... Now, at 61 I feel the cold much more deeply!!!

So glad to see that you are doing so well since the transplant... But I do wish that you would be a bit more generous and share some of that weather with us in the northeast!!!

Oh, BTW, Jerry & I were successful in repairing the TS-520 that we talked with you about about a year ago... I intend to write up the repair details for you. And thank you for the FET that you sent us -- it is being well used!!

Cheers,
Chuck, WA3CEJ

Brrrr, 17 is waaaay too cold for me !!
Right now it is 8PM and we have all the doors and windows open.
It's like a Summers evening here. Clear skies, lots of Stars and WARM !!
I'm Lovin it !!

Chuck,
Please let me know what you guys found on that 520. I am always
interested in that.
I had a TS-830S and a TS-530S in here that both had a weird symptom.
Every time you tried to adjust the idle Current, anything above about 25
or 30 ma would make the IP needle PEG.
It turned out (on both of them) that the Band switch coupler had broken
and somehow bent the top plate of the Neutralization cap down so that it
was touching the next plate.
I'll know exactly what to look for if I ever see that symptom again. I
chased my tail for days on the first unit but went right to it on the
second hi hi.
I really wish I could send some of this nice weather to you guys. I have
relatives in Upstate New York and they tell me it's been a bitter Winter.
My Sister in North Carolina is begging to come stay in my spare Bedroom
for the Winter hi hi
Is Jerry ok ? I sent him an Email a couple of months ago and never
got a reply.
You are Most welcome for the MOSFET
73,
Gordon

Gordon,

Yes, I will follow up on the 520 repair details... I don't have all of the details of it here at the moment, but I can tell you for sure that the low drive was NOT caused by a problem on the RF unit or any of the coil boards...

Yes, Jerry is fine. Much better after back and knee surgeries. If you emailed him and he didn't reply, then the email was never received, I'm very sure!! He's a very close friend (we were just out tonight tipping a few at the local VFW), and I know that he would not ignore an email from you!!

Cheers,
Chuck, WA3CEJ

29315. TS-820S display reading 19.0000

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-15 13:12:56 UTC
From: Peter Carter
Topic: 28723 Message: 29315

Yea I know, this question have been asked 10000 times before, but here is a twist to it.

My TS-820S display was working just fine, then it stopped completely(BLANK). I took it apart as I have done before, cleaned ALL of the contacts, re-soldered some joints, sand down the areas where the screws make contact to the case....basically did all that I can to establish a good contact. Put it back together, turn it on and bingo it worked(so I thought)...well it did but only on the higher bands, on 1.8, 7, and 3.5 it displays 9.000.0., all others are ok.

Question, can this be related to the band switch given that I have cleaned this completely?

Thanks,

29316. Address for K4EAA...

I've not been able to contact Ken via email or phone in the last few weeks. I just wanted to confirm his mailing address before I send him my trusty 830S for it's 25yr physical checkup. Can anyone one confirm his most recent mailing address? Is he possibly on vacation?

Thanks for any help.

Tom,

Ken's address is:
3745 Allenwood St.
Sarasota, Fl 34232

This is the return address off a box of stuff I ordered a couple of month's ago. I suppose it is possible that he is on vacation but usually he will set his e-mail for an auto reply when he is away. I know he suffers from cluster headaches from time to time and I know that it takes him out for a week or so when it happens. I don't know what's up right now but I know that he is usually pretty good about answering his e-mails.

Good morning Peter,

I going to assume the 820 itself is working fine but the digital display is having problems. Is that correct?

Peter,

If you have access to a frequency counter you can check and, if necessary, adjust the 1Mhz reference oscillator in the DG-1 digital display.

With the digital display module installed in the 820 and connected to the plugs, look at the top of the digital display module. There you will see a long row of pins where the display tube, behind the 820 front panel, connects. Next to this row of pins are a row of "3" pins. The 3 pins are, front to back;

Top of the digital display module
<.....> CL2 G CL1 o

The "<.....>" shown above are the multiple pins the display tube behind the front panel plugs into.

The "o" shown above to the right of "CL2 G CL1" is the small hole next to the 3 pins.

You do not need the 3 pin plug as shown in the 820 service manual, page 48. Small alligator clips or small round female sockets attached to the braid and center conductor of a shield cable (short length of RG-174 will do fine) will work. Just be sure you do not short CL1 and G together.

Short "CL2" and "G" pins together.

Connect a frequency counter, cables' center conductor to "CL1" and cables shield to "G".

Power up the 820 and note the frequency displayed on the frequency counter, NOT the 820s' front panel display display.

If the frequency displayed on the frequency counter is NOT 1Mhz +/- 5Hz, use a plastic aligning tool and adjust TC1 through the small hole on the top of the digital display module so the frequency counter displays 1Mhz +/- 5Hz.

Check for proper display of the 820s' digital display bands on ALL bands.

?Chuck's right, Gordon, either I didn't get it or I lost it, but I would never ignore an email from you. Did you send it on the reflector or direct to my k3bz address?
Concerning the 520 which now works very well and looks terrific in Chuck's shack with the rest of his Kenwood gear, a properly detailed technical write-up would have to come from Chuck... he's the brains here... but I can join him equally in thanking you for the parts and the help. The 520 is a gem and I think I learned quite a bit assisting Chuck in its repair.
Speaking of repairs, last year was a humdinger... 4 surgeries and they all went very well. And like the 520, I now have some new parts! Good to hear you are doing well also. Onward and upward!

73, Jerry K3BZ

Gordon,

Yes, I will follow up on the 520 repair details... I don't have all of the details of it here at the moment, but I can tell you for sure that the low drive was NOT caused by a problem on the RF unit or any of the coil boards...

Yes, Jerry is fine. Much better after back and knee surgeries. If you emailed him and he didn't reply, then the email was never received, I'm very sure!! He's a very close friend (we were just out tonight tipping a few at the local VFW), and I know that he would not ignore an email from you!!

Cheers,
Chuck, WA3CEJ

Subject: Re: [TS-520_820_530_830] Re: Sudden Decrease in TS-820S RF output

Chuck,
Please let me know what you guys found on that 520. I am always interested in that.
I had a TS-830S and a TS-530S in here that both had a weird symptom. Every time you tried to adjust the idle Current, anything above about 25 or 30 ma would make the IP needle PEG.

It turned out (on both of them) that the Band switch coupler had broken and somehow bent the top plate of the Neutralization cap down so that it was touching the next plate.
I'll know exactly what to look for if I ever see that symptom again. I chased my tail for days on the first unit but went right to it on the second hi hi.
I really wish I could send some of this nice weather to you guys. I have relatives in Upstate New York and they tell me it's been a bitter Winter. My Sister in North Carolina is begging to come stay in my spare Bedroom for the Winter hi hi
Is Jerry ok ? I sent him an Email a couple of months ago and never got a reply.
You are Most welcome for the MOSFET
73,
Gordon

Gordon, Mike and the group

On this Saturday morning I am getting caught up on all the posts. Gordon I am enjoying the weather as well here in So Cal. It is 72 deg at 7:30 AM and we will be in the low to mid 80â□□s again today. Yes a great day to do antenna work or for that matter go surfing this morning and then to the local mountains to go snow ski in the afternoon. Love So Cal. We do have a lot of houses for sale so all those that are looking for a warm climate there is no excuses now!
I have to tell everyone this is so much fun reading all these posts. I enjoy all of them.
Gordon it is great to hear you are doing so well. Keep it up. Not only for the group but some day I will have to bring you my 820 that I have never found the issue. My old test bench has failed me and I put the 820 on the shelf to come back and look at it another day.
Still only receives strong very local stations, and no RF output. It can transmit and receive across the room on all bands track both Transmit and Receive Audio, Vox, controls all work. So it can work DX to the next room. So some day you can coach me step by step on how to find the issue.
Happy New Year to all
73

Many years ago, I was working on a TS-520 that had a few minor issues - I got it working pretty good but it needed a bit more attention.

I still have it in my basement and plan to get back to it - even though it has been several years since I have been active (and who knows what I will find when I take it out of storage).

Anyway, do any of you guys remember that the 520 originally came with a tapered hex-shaped tuning rod that was used to align the rig?

Am I correct about that? I think the owners' manual mentions it.

As I recall, I stopped working on the radio because I did not have that tool and could not find one anywhere.

Anyone have or know where to get one?

73 to all,

Tim
WU3U

29323. TS-530S is on the way, what type of test equipment should I be looking for?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Topic: 29323 Message: 29323

Most of you who responded to my first post (thank you very much!) know that I'm new to the ham world, as well as to this level of electronics. My working TS-530S is on its way to me and I continue to work through the following books:

ARRL Ham Radio License Manual - Technician
US Postal Service Electrical Fundamentals 1970
FCC Regs Part 97
Getting Started in Electronics - Forrest Mimms III 1983

I am on the lookout for books that you have recommended, such as 1940s-1960s manuals, including John Frye's Basic Radio, but have not had luck yet.

As I scour the thrift shops, etc., looking for books, I might also come across some electronics equipment and am curious what I should be looking for. I see many times that those posting questions are told to test this or that, so it makes sense to have some basic meters/tools with which to work.

I have some basic digital Volt meters and a small analog Micronta, both of which measure Ohms as well. I also have an adjustable Weller soldering station - low end, but not bad. I also have a Weller 140/100 watts soldering gun. I even acquired a work bench, complete with anti-static mat, solution, and a grounded wrist strap a couple years ago. All I was looking for was a bench and the company was closing. The woman said they had sold all of the benches, then realized that one was covered in boxes, etc. When we uncovered it, it was in great shape and had all the grounding straps attached. I'll take it!

Anyway, a local shop has an autoranging capacitance meter for sale. Made by BK for $50 and I'm wondering if that's something worth having for basic diagnostics. I know this is a bit of "cart before the horse", but I can't focus on just studying. I have to spread the "energy" around. It's just how I roll.

So, any thoughts you have on diagnostic equipment that will help you, help me, please speak out.

thanks

I find www.abebooks.com as a very useful site to look for books that are no longer in print .

The prices may vary widely since these are individuals that sell used books .

However I have picked up many real gems for a buck or two .

Usual Disclaimer no financial interest , just a satisfied customer .

Thanks Charlie. I was on there this morning, as I found an old article on John Fyre and the author mentioned ABE as well. I'll dig a little deeper on that site and see what comes up.

Thanks Charlie. I was on there this morning, as I found an old article on John Fyre and the author mentioned ABE as well. I'll dig a little deeper on that site and see what comes up.

Thanks guys. I also just found my Cen-Tech Multi-meter. Certainly not top of the line, but it does the following:

Voltage test
Current test
Resistance test
Capacitance test
Measure Frequency
Continuity and Diode test
Transistor Test

Tom,

I do know that Ken (k4eaa) will only take your rig if you contact him prior to sending any rig AND he will give you a "send to me date." He's really busy...and has a lot of other things going on besides fixin' KW hybrids.

Tom,
Best advice is to Talk to ken before sending any Rigs. I know he is around 2 months backed up at present.

Gordon,

Yeah, too cold for me, too....

Thinking that Florida may be a better place to retire... When I was young (mid 60's) I can remember a bunch of us going up to Vermont to operate November Sweepstakes... Was a blast. It snowed ALL weekend. At the end, we cut the guys on the tower and just let it fall into the 3' feet of snow, loaded it up onto the roof of one of our cars and headed home with smiles on our faces and no issues with the cold weather... Now, at 61 I feel the cold much more deeply!!!

So glad to see that you are doing so well since the transplant... But I do wish that you would be a bit more generous and share some of that weather with us in the northeast!!!

Oh, BTW, Jerry & I were successful in repairing the TS-520 that we talked with you about about a year ago... I intend to write up the repair details for you. And thank you for the FET that you sent us -- it is being well used!!

Cheers,
Chuck, WA3CEJ

There are some people on there that want prices higher than eBay , but many times the same exact book is available for a dollar or two .

I have a nice library of books that I had been looking for , that I found on there where the shipping was more than the book .

I check it often when I remember a book from my past , or see one mentioned on a group as a good reference or circuit book .

I don't think I have ever paid more than $10 for a really hard to find book . It may take me a few months of waiting , but what you are looking for will usually show up at a decent price .

GOOD LUCK !!

Charlie , W5COV

Topic: 29334 Message: 29334

Hello All,

I have been thoroughly enjoying my TS-830S for the past few months after going all through it and bringing it up to excellent operating condition.

This morning, I went to tune up and discovered almost zero drive on all bands when trying to peak the ALC in the tune position. This happened suddenly without warning. I get about 10% meter deflection with no peaking action whatsoever. Of course, I have the carrier control full CW. Same on all bands. Rig manages to show about 10W RF out on all bands. Also, I can twiddle the drive control while watching RF out and see a slight effect. So, I have something going on.

Idling current shows OK at 60ma. HV shows OK at about 900v. SG switch is on. Tried a different 12BY7 I had here and no change. All voltages on the 12BY7 socket check out per K4EAA schematic. That's as far as I got so far.

I checked all previous posts here and see recommendations to change out R5 & R6 on the rectifier board. Also I see that Q22 and Q29 on the IF board have been problematic. However, I don't have anything to replace them with here right now.

I'm going back down to the shack right now to investigate further. Any suggestions out there as to what I might look for? I have a spare set of finals that I'm going to try - but I don't think that there's much chance they would go out so suddenly.

Regards, Alan WB2FZC

Update....

Just checked the voltages in the final unit and found 130v. on pin 3, screen grid, of each 6146B. This is about half of the expected 264v. Tracing through, I also get the same 130v. at pins PD2 & SG1 on the rectifier unit.

This points to looking at the two resistors R15 & R16 on the rectifier board mentioned in a previous post (must have been a typo previously as R5&R6 were stated). I measured them in circuit and get about 35K on each. However, I did a little "wiggling" of R16 with the test lead and she jumps to near continuity, so I have something going on there. I'll pull the board tomorrow, pop the resistors and check them and check all soldering.

Note that my digital fluke was jumping around trying to find a value. Hard to see what was going on. So, I pulled out my Simpson analog to take a look. You could see the drop immediately on the good ole analog meter.

Any other ideas?

Regards. Alan, WB2FZC

Greeting Group!

Took another closet queen out to see why the 2 high bands were not working correctly. The big tip off was the display. I figured..what the heck..let's check the PLL for proper freq's. All was good until the 29 & 29.9 Mhz bands. I could not get proper frequency on my counter. I was following the procedure in the service manual on Pg 52 # 5-2.

I pulled the PLL out and took a look inside. 2 screws were missing that hold down X60-1010...so..continued to dismantle the unit and on the VCO found 2 XTALS, X9 & X10 that were obvious not from the factory. Missing the blue plastic wrap with the freq. on it..etc. These were straight metal cans with freq on the top. X-9 was 32.500MHZ & X10 was 33.00MHZ. Doin' a bit of cypherin',... this mod let the rig cover most all of the 26 & 27 MHz bands..with a touch into 28MHZ. Now gotta go dig through some parts and find some replacements.

I up loaded some pictures. It will be listed under TS-820(S) CB HACK

Hi Alan,

Either the body/bodies of the resistors are cracked/broken (discoloration/burnt looking) or the PC boards' foil and solder connection has failed.

The resistors, R15 and R16, form a voltage divider on the Rectifier Unit and only in TUNE mode. The normal screen voltage to the final tubes, CW, USB, and LSB Mode switch positions, originates at the Rectifier Units' "SG2" terminal. When the 830 is placed in TUNE mode the screen voltage flows from the "SG2" line on the Rectifier Unit through R15 and R16 with the screen voltage being applied through the Mode switch, in TUNE Mode, at the junction of R15 and R15 on the Rectifier Unit. This results in a lower final tube screen voltage at the Rectifier Unit's "TUNE" terminal, to both final tubes to protect the final tubes during tune up.

If either of the resistors have failed, for what ever reason (resistance has increased significantly, resistors are burnt/cracked, or the solder connection on the PC board foil has failed), the final tube screen voltage will be significantly less than the normal screen voltage which results in a significant reduction in power output.

One other thing. If you can tune the 830 up in CW mode to full output but TUNE mode results in less than normal power output, then that is a clear sign that resistors R15 and R16 are the source of your problem. As you said, moving the resistors with a plastic tool causes the screen voltage to abruptly change in TUNE mode, that too is a clear sign of a problem with the resistors and/or the circuit board solder connections.

Mike,

All that you have said makes sense but I do not get full power in the CW mode either. Maybe something else is going on also. I'll check further tomorrow on the SG2 circuitry and let you know.

Alan, WB2FZC

> One other thing. If you can tune the 830 up in CW mode to full output but TUNE mode results in less than normal power output, then that is a clear sign that resistors R15 and R16 are the source of your problem. As you said, moving the resistors with a plastic tool causes the screen voltage to abruptly change in TUNE mode, that too is a clear sign of a problem with the resistors and/or the circuit board solder connections.

> > The resistors, R15 and R16, form a voltage divider on the Rectifier Unit and only in TUNE mode. The normal screen voltage to the final tubes, CW, USB, and LSB Mode switch positions, originates at the Rectifier Units' "SG2" terminal. When the 830 is placed in TUNE mode the screen voltage flows from the "SG2" line on the Rectifier Unit through R15 and R16 with the screen voltage being applied through the Mode switch, in TUNE Mode, at the junction of R15 and R15 on the Rectifier Unit. This results in a lower final tube screen voltage at the Rectifier Unit's "TUNE" terminal, to both final tubes to protect the final tubes during tune up.
> >
> > If either of the resistors have failed, for what ever reason (resistance has increased significantly, resistors are burnt/cracked, or the solder connection on the PC board foil has failed), the final tube screen voltage will be significantly less than the normal screen voltage which results in a significant reduction in power output.

Subject: [TS-520_820_530_830] TS-820(S) CB/Free Band Hack

Greeting Group!

Took another closet queen out to see why the 2 high bands were not working
correctly. The big tip off was the display. I figured..what the heck..let's
check the PLL for proper freq's. All was good until the 29 & 29.9 Mhz bands. I
could not get proper frequency on my counter. I was following the procedure in
the service manual on Pg 52 # 5-2.

I pulled the PLL out and took a look inside. 2 screws were missing that hold
down X60-1010...so..continued to dismantle the unit and on the VCO found 2
XTALS, X9 & X10 that were obvious not from the factory. Missing the blue plastic

wrap with the freq. on it..etc. These were straight metal cans with freq on the
top. X-9 was 32.500MHZ & X10 was 33.00MHZ. Doin' a bit of cypherin',... this mod

let the rig cover most all of the 26 & 27 MHz bands..with a touch into 28MHZ.
Now gotta go dig through some parts and find some replacements.

I up loaded some pictures. It will be listed under TS-820(S) CB HACK

I just wanted to say a big thank you to all of the knowledgable people in this group. I've been through my TS820S from top to bottom and it is performing factory fresh. Tomorrow is VE testing, so by this time tomorrow night I should have my General and will be able to fully enjoy this fine piece of radio gear. I've received excellent signal reports on 10 meters and am looking forward to exploring more of the bands, Tom KD7CDC

Alan,

You might consider connecting your DC voltage meter (set to measure at least 300VDC) to the Final Unit's SG terminal and chassis ground. Set the Mode switch to TUNE then CW or all sideband positions. There should be a difference the voltage, TUNE mode being less. This test will determine whether there is a break in the wiring to and from the Mode switch.

Also, as you said, if "wiggling" or "moving" resistors R15 and R16 causes the SG voltages on the Final Unit to change or become erratic then I would look for a bad solder connection on the Rectifier Unit.

While you are checking voltages on the Rectifier Unit, visually watch the relay RL1 on the Rectifier Unit when switching the rear panel SG switch from ON to OFF and back ON again. The relay on the Rectifier Unit should energize in the OFF position but not in the ON position. You should see AND here it change with the different positions of the SG switch on the rear panel. Just be sure you leave the SG switch in the ON position when finish.

Just a few other places to check.

Hi Joe,

Followed the thread and asking myself if you can hear the calibrator ????

Had some '520 and never used anything other than the internal calibrator to
do the alignment job !

The user's manual is clear enough, even for someone with common, not
extraordinary.. skill, and there is a service manual downloadable all over
the web, just google a bit.

The calibrator usually goes up to +20dB over 9 on 80, about S9 on 20 and
about S6-7 on ten meter.

Just my two eurocents...

Good luck and be patient, it will come alive, I promise you !

Joe,

If you remember the discussions about how CB hackers modify the TS-520s RF Unit HET OSC crystals to operate on 11 meters, the CB hackers, as you have found out, do a similar modification to the 820s' PLL Units' crystals to make the 820 operate on 11 meters.

The different crystals you found in the 820s' PLL Unit result in a different "VCO" signal to appear on the RF Units' "VCO" terminal allowing the 820 to operate on 11 meters or other non-ham bands. Good job on using simple math calculations to determine and actually see what has been done to your 820.

If you do not have replacement crystals from an 820 parts radio, you can buy them from International Crystals in Oklahoma City, OK

http://www.icmfg.com/hamradio-manufacturers.html

Alan
I have had this same problem several times with the TS-830s that I restored. My problem was caused by a bad connector pin on the TIFF signal. Check out the ts-830 Survival Guide available at several sites on the internet. Look for the problem "Loss of ALC". The info here will give you the specifics to fix the problem.

Good Luck

The normal screen voltage to the final tubes, CW, USB, and LSB Mode switch positions, originates at the Rectifier Units' "SG2" terminal. When the 830 is placed in TUNE mode the screen voltage flows from the "SG2" line on the Rectifier Unit through R15 and R16 with the screen voltage being applied through the Mode switch, in TUNE Mode, at the

junction of R15 and R15 on the Rectifier Unit. This results in a lower final tube screen voltage at the Rectifier Unit's "TUNE" terminal, to both final tubes to protect the final tubes during tune up.
> > >
> > > If either of the resistors have failed, for what ever reason (resistance has increased significantly, resistors are burnt/cracked, or the solder connection on the PC board foil has failed), the final tube screen voltage will be significantly less than the normal screen voltage which results in a significant reduction in power output.

From: Bill Scurlock
Topic: 29351 Message: 29351

I have a very nice TS-830S, s/n 4090097, that I have decided to sell. All the filter positions are full, the HV capacitors replaced, 1N5711 diodes have been installed in the product detector and balanced modulator, it has the KB-1 weighted tuning knob, and the USB and LSB carrier frequencies have been adjusted using Spectrogram to equalize frequency response. This radio has been used on a regular basis since I refurbished it 4 or 5 years ago. To the best of my knowledge, everything functions properly on this TS-830S. If you are interested in purchasing a radio in this condition, please send me an email at "k5gcw at sbcglobal.net" and I will send you more information and photos.

This radio will only be sold and shipped within the contiguous United States.

Thanks and 73, Bill, K5GCW

Paul & Mike,

Problem solved. Went in and re-soldered R15 & R16 and saw no change. I then pulled the TIF connectors on the IF and RF boards, cleaned them and re-seated them. Full ALC. Back in business. Thanks guys.

It's funny. I have the survival guide and saw that section, but it was titled "intermittent" ALC, so I breezed right past it. A few months ago, I cleaned and re-seated all connectors but I bet I skipped the TIF connector on the RF board because it was inaccessible underneath the counter board. This time I pulled everything out that was in the way and cleaned it.

Again, thanks to both of you for taking your time to help. It means a lot and you both saved me a ton of time.

Regards, Alan WB2FZC

If you can tune the 830 up in CW mode to full output but TUNE mode results in less than normal power output, then that is a clear sign that resistors R15 and R16 are the source of your problem. As you said, moving the resistors with a plastic tool causes the screen voltage to abruptly change in TUNE mode, that too is a clear sign of a problem with the resistors and/or the circuit board solder connections.

Mike & Group,

Mike, thanks for your nice comment. I found another "PLL/VCO/PD BOX" and tried it..still had same problem. I found another in the parts box...and tried that one..BINGO. I opened up the 1st replacement and..gee..guess what! That one had been modified also. No wonder I have gotten them for real cheap. Good training & practice. Oh well. Think I'll get some xtal's from the place you stated below so I have some good spare stuff around. Tnx fer all the help you have given me and others..it's been REAL helpful!

Subject: [TS-520_820_530_830] Re: TS-820(S) CB/Free Band Hack

Joe,

If you remember the discussions about how CB hackers modify the TS-520s RF Unit HET OSC crystals to operate on 11 meters, the CB hackers, as you have found out, do a similar modification to the 820s' PLL Units' crystals to make the 820 operate on 11 meters.

The different crystals you found in the 820s' PLL Unit result in a different "VCO" signal to appear on the RF Units' "VCO" terminal allowing the 820 to operate on 11 meters or other non-ham bands. Good job on using simple math calculations to determine and actually see what has been done to your 820.

If you do not have replacement crystals from an 820 parts radio, you can buy them from International Crystals in Oklahoma City, OK

> > > >
> > > > One other thing. If you can tune the 830 up in CW mode to full output but TUNE mode results in less than normal power output, then that is a clear sign that resistors R15 and R16 are the source of your problem. As you said, moving the resistors with a plastic tool causes the screen voltage to abruptly change in TUNE mode, that too is a clear sign of a problem with the resistors and/or the circuit board solder connections.

> > > > >
> > > > > The resistors, R15 and R16, form a voltage divider on the Rectifier Unit and only in TUNE mode. The normal screen voltage to the final tubes, CW, USB, and LSB Mode switch positions, originates at the Rectifier Units' "SG2" terminal. When the 830 is placed in TUNE mode the screen voltage flows from the "SG2" line on the Rectifier Unit through R15 and R16 with the screen voltage being applied through the Mode switch, in TUNE Mode, at the junction of R15 and R15 on the Rectifier Unit. This results in a lower final tube screen voltage at the Rectifier Unit's "TUNE" terminal, to both final tubes to protect the final tubes during tune up.
> > > > >
> > > > > If either of the resistors have failed, for what ever reason (resistance has increased significantly, resistors are burnt/cracked, or the solder connection on the PC board foil has failed), the final tube screen voltage will be significantly less than the normal screen voltage which results in a significant reduction in power output.

29358. Adjustments on bottom of TS-530S and other tuning items

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-16 22:23:39 UTC
From: nelsonsb66
Topic: 29358 Message: 29358

I see some adjustment places on the bottom of the rig, and cannot seem to find a reference on what they are for, or how to use them. They are:

Carrier F. Adj (CWT/USB/LSB)
Std Osc F. Adj

I am getting my rig ready for use after 15+ years in storage and have finished both the recieve and transmit tuning listed in the manual. The signal wave form on my scope looks good - not a perfectly smooth edge to the waveform, but just very small variations.

Also, in tuning it up, I noticed that the rig does not transit on 12M at all - all the rest of the bands work just fine. The WARC connection has been severed according to instructions to allow all bands to transmit, and both 30M and 17M work very well. Any ideas?

Lastly, when I use 10 or 15 M, I seem to need to crank up the carrier to maximum (or near) to get any signal strength. I am concerned that I am overdriving the circuit with either the end result being signal distortion, circuit failure, or both. I do not see this behavior on any of the other bands (other than 12M as listed above).

Any help is appreciated!

Hello,
I have been repairing a kenwood ts-820s . This is about the digital display problems.
The problem was a display stuck on 9000.
As mentioned on the net by others I had resoldered the 2 pcbs .cleaned them up .the connectors cleaned.
So after this the 1.8 mhz to 14 mhz displayed the correct frequency.
However, from 21 mhz and up the display was lite up but the frequencies varied with no lock.
I had readjust the TC1 trimmer on the IF board.As well found a nice spot in the T1 and T2 xfmrs so 21 mhz band would work on the display.As well the 1.8 to 14 mhz bands still functioning .
but the 28 mhz bands still do not function on the digital readout.
Is one of the amplifiers in the stream lacking amplification to provide signal to the display boards ?
Is it a alignment problem ? or a old changed value part ?
Still working on here at the shack.
Any one have any ideas .?
Thanks Anthony ve4akf

Anthony,

I just got done removing a "CB" hack job on an 820S..(.see a few post back). The higher bands, 28 - 29.5Mhz range were affected by the "retuning" of the transformers in the PLL. Might want to check there to see. Procedure and frequency values are in the service manual starting on Pg 52 ... Section 5-2-1. Good Luck.

Topic: 29358 Message: 29362

Hi Nelson,

The holes on the bottom are there to adjust, when needed (alignment) the PLL Unit's CAR and individual VCO Oscillators without having to remove the cabinet.

Unless there is evidence, through troubleshooting and testing, that points to one or more of these adjustments through the bottom of the 530s' cabinet, do not mess with them.

If the CAR control, in TUNE and/or CW mode must be turned much higher that 12 o'clock and/or almost completely CW, to achieve any level of power output during tune up in TUNE and CW mode, that could be caused by a number of things

1. Weak driver tube
2. Weak finals
3. Improper alignment
4. Improper tune up methods used
5. LV (210 and 300 volt) and HV power supplies
6. Bad connections in/on the individual PC board plugs and pins, there are a number of them throughout the 530.
7. Broken PC board foil runs to the PC board pins due to age, shock, mishandling, or bad soldering at the factory or previous owner

and/or other possible failures.

Loos of RF power output on any band quite often, but not always, results in loss of both receive and transmit This is assuming there isn't any other failures in the PLL Carrier and VCO circuits and VFO circuitry etc. The PLL Unit which contains the VCO, CAR, and VFO input controls both transmit AND receive. A failure in any one of these circuits will affect, cause failure to occur, in both transmit and receive.

There is a terminal on the RF Unit labeled "VCO". This terminal is where the PLL Unit's VCO signal for ALL bands is applied to the RF Unit. If you have access to an o'scope and frequency counter, you might monitor the RF Unit's "VCO" terminal between transmit and receive on 12 meters. The 12 meters VCO signal should be present in both receive AND transmit.

You didn't state what you level of technical skills, troubleshooting and repair, of electronic gear is. This is not meant be disrespectful so please don't take it that way. If you skill level is limited, maybe even non-existent, I would recommend finding a local ham who has the skills in troubleshooting and repair to assist you. If you skills are up to it, I recommend, if you do not current hold, the operators and service manuals at Gordons' website

www.n6wk.com/kenwood/

These manuals will help you track down the source of your loss of RF output. Take voltage readings and compare them with the service manual. Tap "lightly" on the IF Unit relay to

see if the symptoms change. If they do then it's quite possible, after a thorough visual inspection of the foil side of the board where the relay and surround components are attached and soldered, could be the source of your problem.

29363. TS-520SE SENSITIVITY QUESTION

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-17 22:08:42 UTC
From: Charles
Topic: 29363 Message: 29363

I'm still quite new to the world of hybrids and I've noticed that the sensitivity of my 520SE is significantly less than that of my TS-940. (Yes, I appreciate that the 940 is a more advanced model with greater capabilities.)
Basically, using the same dipole, a reasonably strong and clear SSB signal on the 940 will barely be heard on my 520SE, if at all. I do have wonderfully clear reception on "SOME" strong stations with my 520SE, but there seems to be a considerable lack of sensitivity for many other weaker signals.
I haven't made any calibration tests or adjustments as of yet because the rig is a mint condition model that looks like someone bought it, tried it a few times, and then stuck it on the shelf for many years and never messed around with any factory settings. I also realize that you can't tell anything by appearance alone. It's only an opinion of mine.
Question: Is this lack of sensitivity the usual level of performance for this radio?

From: Daniel TOESCA
Topic: 29363 Message: 29364

Hi Charlie,

As a ballpark idea, the 520"s internal calibrator level is usually around S9 on 20 meter, S9+20 on 80 meter and S6-7 on 10 meter.

If you connect both of your sets together through the antenna connector - BEWARE !!! DO NOT TRANSMIT !!! - you can monitor this calibrator level and appreciate if there is any difference.

Or build a simple signal source using a cheap Xtal, 3.579 MHz color-burst is OK - adjust its level for about S5 on your 940 and check you 520 thereafter.

Causes of loss of sensitivity are many, and the simplest ones are : bad bandswitch contacts (use some contact spray and rotate them several times) - relay issues - maybe component issue = RF amplifier MOSFET zapped - maybe alignment issues.

Check the calibrator level and the bandswitch first.

Charlie,

The sensitivity of all the KW hybrids is very good to excellent. Some others in the group may back me up..but..get yourself some DE-OXIT. Turn OFF rig, let it sit for about 1/2 hour..then measure the HV caps to MAKE SURE that all the voltage is gone. THERE ARE LETHAL VOLTS IN THERE! You don't need to make the XYL a widow. Take every connector you can off...use some DE-OXIT, reapply/remove the connectors several times each. Also...use it on every multi-wafer switch, pot, and other controls. Blow off residue with "caned air." You can get at ...I think Walmart...I get mine from Costco..in a 6 pack. Make sure that all connectors are properly seated..and fire off the rig. I have been astounded at the results of cleaning the controls/connectors, especially after a rig has sat for awhile. Good Luck.

The rig hasn't been used much, or so it would appear. There's been 2 responses to the original question and both suggest a connector problem. This makes perfect sense to me. Daniel and Joe, thanks for your suggestions. I'll try and clean those contacts within the next day or two. I'll respond to this message thread with the results just as soon as I can.
Thanks for your help.

hello, I went to the manual section as you said.I have tried the 28 mhz coil vco adjustment. it is delicate to adjust but I know good to go slow.
it did not stabalize the display on this band.This adjustment not doing the trick. I did check the vco voltages before and was good.
Possible the transfomers underneath the shielding in the PLL unit need adjustment.I would have get at it maybe.
T1,T2,T3 of board X50-1340-00 of from the Q21 .I think this is prt of the loop circuit as signal path follws here.
Well any sugestions ? Parts or something changed value or something. I only have the service manual , a DMM and a VTVM here and solder station.
Ill keep on it hope I can fix it up .
Thanks Anthony

Tony,

Does the 820, by itself work on all bands even though the digital display displays the wrong frequency on the higher bands? You can test this by disconnecting the plug on the bottom of the digital display, it's an edge type plug/connector. If the 820 works fine without the digital display then the problem is more than likely not in the 820 but rather in the digital display unit.

Have you checked the digital display units' internal 1Mhz reference oscillator frequency? If not and you have a frequency counter, do the following:

1. Short the CL2 and G pins together on top of the digital display unit.

2. Connect the frequency counter to pins CL1 and G on the top of the digital display

The frequency counter display should be 1Mhz +/- 5Hz. If not then adjust TC-1 through the small hole on the top of the digital display unit so the frequency counter displays 1Mhz +/- 5Hz.

The "CL1", "G", and "CL2" pins are the "3" pins at the top rear of the digital display unit. They are separate from the multiple pins that connect the digital display tube behind the front panel to the digital display unit. The pins are front to back, CL2, G, CL1.

Hello, Thank you for the information.
I have been in contact with AK4AA and also YV5ABH about the problem in my kenwood ts820s
At first the display was intermittant etc . would show 9000 ..
So I had resoldered the 2 counter boards and cleaned them up .Also those pins for the pcbs.
So at this point 1.8 mhz to 14 became to function.
21 to 29 mhz bands the display still light up but digits rolling around changing .No lock .
Since I have limited equipment .A VTVM with not much frequency response ,A DMM , a wave meter, solder station I can only do so much.But I have the rig as well to tell me whats is what.
I had adjusted the TC1 trimmer in the IF and adjusted the coils in the counter board so that 21 MHZ would show correct display and also 1.8 to 14 MHZ display good.
The adjustments made by going slow turning and watch the display and listening to the receiver and the meter.
So now the 10 meter bands do not lock in .The display still rolls about changing digits.
It was told to me that AK4AA had solved this problem.and with help of YV5ABH they informed me that an unwanted frequency component is disrupting the counter circuit at the higher bands in the PLL .Suspected part faluire is the IC number SN76514N. or a component tied in the circuit somewhere.
The solution of AK4AA was to install a LC cicuit in the counter filter section.
A 330 pf cap and a 1.3 uH inductor.to trap out the unwanted frequncy component.Much time and effort gone into that to find out as well as laboratory grade equipment.
It is obvious a part changed value some where or a fault in an IC occured.
So now I am looking for a 1.3 uH coil. It is difficult to find one . I do not have any toroid forms and or test equipmet to wind one and find the freqeuncy.
I had bought the old kenwood from a fellow ham up here.Has some problem but want to fix it up good.For me that is ham radio always improving and fixing the station .
So thats my story.Still working on it .
Looking for a coil now .
Thank you .

> The rig hasn't been used much, or so it would appear. There's been 2 responses to the original question and both suggest a connector problem. This makes perfect sense to me.
> Daniel and Joe, thanks for your suggestions. I'll try and clean those contacts within the next day or two. I'll respond to this message thread with the results just as soon as I can.
> Thanks for your help.
>

I got a break today: we had snow and the freezing rain so my chores were canceled :) I went over and familiarized myself with the "innards" of the 520SE, spraying contact cleaner and oiling (clock oil) the variable capacitor bearings as I went.
I also used contact cleaner on the MFJ-986 tuner that I'm using that has been sitting on the shelf for 12 years (hmmmmm?) and, between the two pieces of equipment, I was successful. The sensitivity is "good" but does not compare to the TS-940 but that should be expected, I guess? Sensitivity has greatly improved, so it's "mission accomplished."
My thanks again to Daniel and Joe for their input.

I've been considering buying an external VFO for my 520SE but after looking at the schematic for the internal VFO and comparing it to the external VFO, I don't seen much of a difference. In fact, they look the same with the exception of the switches and indicator lights and a few other bits.
I don't have an "EE" degree and I'm new to hybrids, but I don't see a significant advantage to having an external VFO. Am I missing something obvious? Is there a clear-cut advantage in using an external VFO?
Constructive input is welcome.
Thanks.

Hi Charlie,

There are two advantages if you consider either a value to you.

1. You can work split frequency or jump to another frequency quickly.

2. The external VFO's sometimes offer less drift/better stability. The external VFO will not have to endure the temperature build-up/swing as the one in the radio which is affected

By the heat generated from the 12BY7A driver tube. I have seen less drift in the past using a remote VFO on practically every hybrid I have owned (Kenwood and Yaesu).

FWIW,

Greg

Charlie,

Having the external VFO will allow you to work on two different frequencies at the same time. TX on one and RX on the other. Alot of DX stations will call on one freq. and listen on another. Unless you are able to work split freqs. you will be unable to work those stations. Some DX is cross band...TX on 10m and listen on 20m or something like that.

Thanks for the great group.

Recently, I lost ALC meter movement during tuning on 10 and 20 meters. I replaced the driver tube, all came back. Now, 2 weeks later, I've lost everything on 20 meters. No ALC meter movement during tuning, no power output, but also, nothing on receive. I can't hear a thing.

I can have as many conversations on 40 as I wish, but I sure miss 20. Appreciate any suggestions.

29377. TS-820 AF AVR Unit board

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-19 05:29:43 UTC
From: w5rkl
Topic: 29377 Message: 29377

If you find yourself working on an 820 that has a bad AF AVR Unit board. Don't rush out and buy any old TS-820 X49-1080-00 AF AVR Unit board off eBay or from a parts radio. Why? Because not all TS-820 X49-1080-00 AF AVR Unit boards are the same!

First, turn the bad board over and note the number coated with solder on the foil side. The number could be

J25-1381-03

or

J25-1381-13

or some other number. The number on the back of the replacement board MUST be the same as the number on the back of your bad board. If they are not the same, the replacement board will not work in your 820!

The major difference between the TS-820 AF AVR Unit boards is on plug AF3! This plug routes the VFB signal, AV1 audio, AV2 audio, MON (Monitor) audio, and a few other signals into and out of the board.

The one glaring symptom will be complete loss of audio to the speaker, regardless of the volume control setting. This could lead you to believe Q3 on the board is bad. That is not necessarily true. What most likely has happened is you purchase a different "factory" designed AF AVR Unit board that is not compatible with your 820!

So, if you have to replace the 820s' AF AVR Unit board make sure you check and note the number on the foils side of the board so when you buy a replacement board from a parts seller or parts radio, the replacement board has the same exact number on the foil side as your board has! The X49-1080-00 number does not means all AF AVR Unit boards are the same!

How do I know this? I just bought a board that had a different number on the back, it had a suffix of "03" and not a suffix of "13" that my board had. I'm telling you so you don't make the same mistake I did!

I believe the chief advantage is in split frequency operation.

With an external VFO you can quickly switch between two frequencies.

Operating "split" is an advantager only if you are an avid DXer where DX stations listen on a stated frequency and transmit on another, usually beyond the "RIT" capability.

Yes.

The Xverter, TV-502 2 meter or TV-506 are nothing more than transmit and receive converters between the 520 and the TV-502 2 meter converter or TV-506 6 meter converter.

The 520 operates on 10 meters when using the TV-502 or TV-506 converters. The 520s' final amplifier is disabled when using the TV-502 or TV-506 converters.

The basic conversion is as follows:

Transmit:

The 520s' 10 meter transmit signal is applied to the TV-502 or TV-506 converters where it is "up converted" to 2 or 6 meters.

Receive:

The 2 or 6 meter signal is "down converted" to 10 meters where it is applied to the 520. The 520 processing the "down converted" 28Mhz signal as it normal would for a 10 meter signal.

The VFO is NOT disabled when using the TV-502 or TV-506, 2 or 6 meter converters. Therefore, you can use the internal and external VFOs when using the TV-502 or TV-506 2 and 6 meter converters.

Dave,

Since the other bands are working, more than likely what has happened is the RF Units' 20 meter heterdyne crystal has failed to oscillate. When this happens both transmit and receive will fail on 20 meters.

The 20 meter heterodyne crystal is 22.895Mhz. If it is found to have failed completely, not due to dirty wafer switch contacts or any broken connections at the switch or crystal leads, you can order a replacement from International Crystals in Oklahoma City, OK

http://www.icmfg.com/hamradio.html

They have an 800 toll free number you can call to place the order.

Having said that, make sure the 22.895Mhz 20 meter HET crystal has, in fact, failed. You do not want to order a replacement to find out the problem was a dirty band switch wafer, broken wire/connection to the 20 meter wafer tab on the RF Unit and not an actual crystal failure. So make sure before you order.

Typically, a replacement 22.895Mhz crystal will cost around $22 plus approximately $3 USPS shipping. You may have heard that International Crystals is charging "$50" or more for replacement crystals. This is true ONLY for crystals with frequencies of 5Mhz and below, not true for crystals with frequencies above 5Mhz.

Charlie,

Glad to hear that "it's alive." If you can, check out the "basic alignment" procedure in the operators manual. It's rather easy and, may add some more ears. Not too long ago I got a "non-working" 820S for free. The guy didn't want it and was just going to toss it. Well, got it home and something obviously had been spilled on/in it. Looked like coffee with cream & sugar....that had been there for a while... well, took some DE-OXIT, small paint brush and about 2 hours. It's still hummin' away.

> Thanks for your help.
>

I got a break today: we had snow and the freezing rain so my chores were canceled :) I went over and familiarized myself with the "innards" of the 520SE, spraying contact cleaner and oiling (clock oil) the variable capacitor bearings as I went.

I also used contact cleaner on the MFJ-986 tuner that I'm using that has been sitting on the shelf for 12 years (hmmmmm?) and, between the two pieces of equipment, I was successful. The sensitivity is "good" but does not compare to the TS-940 but that should be expected, I guess? Sensitivity has greatly improved, so it's "mission accomplished."
My thanks again to Daniel and Joe for their input.

I want to add a Kenwood 830s or 830 Gold to my Kenwood collection. Of course it must have all the filters (especially CW) and be in good working order. This will be UK only unfortunately as US - UK postage costs are stupidly ridiculous.
I can collect within a 100 mile radius for my QTH in Barnard Castle..see G4FUT QRZ.com for details.
Happy New Year to all.

Subject: [TS-520_820_530_830] TS-820 AF AVR Unit board

If you find yourself working on an 820 that has a bad AF AVR Unit board. Don't rush out and buy any old TS-820 X49-1080-00 AF AVR Unit board off eBay or from a parts radio. Why? Because not all TS-820 X49-1080-00 AF AVR Unit boards are the same!

First, turn the bad board over and note the number coated with solder on the foil side. The number could be

J25-1381-03

or

J25-1381-13

or some other number. The number on the back of the replacement board MUST be the same as the number on the back of your bad board. If they are not the same, the replacement board will not work in your 820!

The major difference between the TS-820 AF AVR Unit boards is on plug AF3! This plug routes the VFB signal, AV1 audio, AV2 audio, MON (Monitor) audio, and a few other signals into and out of the board.

The one glaring symptom will be complete loss of audio to the speaker, regardless of the volume control setting. This could lead you to believe Q3 on the board is bad. That is not necessarily true. What most likely has happened is you purchase a different "factory" designed AF AVR Unit board that is not compatible with your 820!

So, if you have to replace the 820s' AF AVR Unit board make sure you check and note the number on the foils side of the board so when you buy a replacement board from a parts seller or parts radio, the replacement board has the same exact number on the foil side as your board has! The X49-1080-00 number does not means all AF AVR Unit boards are the same!

How do I know this? I just bought a board that had a different number on the back, it had a suffix of "03" and not a suffix of "13" that my board had. I'm telling you so you don't make the same mistake I did!

A few months ago I bought a TS-820S "tech special" at a hamfest. I repaired the problems in it and then decided to look for a VFO-820 to go along with it.

I bought a nice looking one on eBay. It was obvious from the picture that it did not have the spinner knob, instead having the older style non-spinner knob. What was not obvious from the picture, was that the cabinet color was not the khaki color of my TS-820S and all the other hybrids that I've seen. This vfo is gray. This is not a repaint job by a previous owner unless he was an expert. Inside and out, this appears to be factory. Did Kenwood ever produce the VFO-820 in gray?

I'm not sure at this point whether to repaint the VFO-820 cabinet to match the TS-820S and maybe someday replace the knob with a spinner type or just sell this one and buy another one that already matches. I hate to change the color on it if in fact this is the original color.

29393. Re: TS-820 AF AVR Unit board

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-19 20:52:53 UTC
From: w5rkl
Topic: 29377 Message: 29393

If you download the 820 "service manual", look at the AF AVR Unit schematic on page "58", then download the 820 "operators'" manual and look at the AF AVR Unit schematic on page 31, you will instantly see the differences in AF AVR Units' AF3 plug pins.

The AF AVR Unit boards, placed on a desk, side by side, look the same. The X49 numbers are also the same, no difference in suffix. What makes them different is the foil side solder mask numbers. My original factory AF AVR Unit board had

J25-1380-13

on the foil side. The spare board I bought had

J25-1380-03

on the foils side.

While looking at the "service manual", page 58, showing the xray component and foil side of the board, I noticed the xray board has the number "J25-1380-03" clearly showing but the schematic appears to be for the "13" suffix board. What caught my eye on the boards' xray photo was the presence of R45 and R46 shown. Those components are NOT on the "13" suffix boards! The only component on the foil side of a "13" suffix board is a disc capacitor between amplifier chip Q3 pins "2" and "5".

The important issue here is to pay attention to the board numbers on the foil side of the board and not just the X49 number on the component side of the board. All of the boards in the 820, and I'm sure the other hybrids as well, have these numbers. I too, thought the boards were interchangeable but I found out, first hand, they are not.

I just thought it was important to let folks know to pay attention to the board numbers (foil side) to ensure any replacement boards they were going to use had the same numbers and the boards were compatible. It is an "easy" mistake to make, anyone would have made the same mistake. For the 03 suffix board to work in a 13 suffix wired 820, the wires on the AF3 plug would have to be rearranged by pulling them out and placing them in the appropriate holes in the plug. That can very easily result in broken wires. Therefore, I do not recommend doing that.

Topic: 29375 Message: 29394

If you have access to a RF signal generator that tunes through 22 Mhz, tune the generator to 22.895Mhz. Set the generators' output signal level to a low level and inject the signal at TP3 on the RF Unit. Set the 520s' band switch to 20 meters, and connect an antenna to the 520. You should now hear 20 meter signals.

If the receiver comes to life on 20 meters then that indicates the 20 meter, 22.895Mhz, het osc crystal is bad.

Again, as I said before, make sure you have checked and cleaned the band switch wafers before performing this test to ensure the band switch wafer is not the source of the problem. Also check wiring to the switch wafer to ensure there are no broken wires.

The above test is easy to do, all you need is a simple RF signal generator. I recommend using a .01ufd 50VDC or .1ufd 50VDC disc capacitor between TP3 and the signal generators' output. This will isolate the generator, "DC wise", from TP3, preventing any DC voltage from being applied to TP3. All you want at TP3 is an RF signal from the generator, no DC voltage.

> While looking at the "service manual", page 58, showing the xray component and foil side of the board, I noticed the xray board has the number "J25-1380-03" clearly showing but the schematic appears to be for the "13" suffix board. What caught my eye on the boards' xray photo was the presence of R45 and R46 shown. Those components are NOT on the "13" suffix boards! The only component on the foil side of a "13" suffix board is a disc capacitor between amplifier chip Q3 pins "2" and "5".
>
> The important issue here is to pay attention to the board numbers on the foil side of the board and not just the X49 number on the component side of the board. All of the boards in the 820, and I'm sure the other hybrids as well, have these numbers. I too, thought the boards were interchangeable but I found out, first hand, they are not.
>
> I just thought it was important to let folks know to pay attention to the board numbers (foil side) to ensure any replacement boards they were going to use had the same numbers

and the boards were compatible. It is an "easy" mistake to make, anyone would have made the same mistake. For the 03 suffix board to work in a 13 suffix wired 820, the wires on the AF3 plug would have to be rearranged by pulling them out and placing them in the appropriate holes in the plug. That can very easily result in broken wires. Therefore, I do not recommend doing that.

Joe,

The power supplies, 3.3VDC and 9VDC, on the boards are the same as are the pins on AF1 and AF2 plugs. No difference there. The significant differences is on plug AF3.

I remembered some time ago, a year or so maybe, I saw 2 different AF AVR Unit schematics. At the time I wasn't replacing or buying spare boards so I ignored it. The seller is sending me the correct "13" suffix board, free, and told me to keep the "03" suffix board. Nothing lost but a lot gained.

Modifying the boards pins is not possible since the foil side is different between the boards. It's also not a good idea to pull the pins on plug AF3 so they match the pins on the 03 suffix boards. Too risky which can result in broken wires. Remember, the 820 is quite old and age can take its toll on the plug wires and internal female sockets.

I agree, all the KW's I've seen/owned have been gray...over the years I think KW may have adjusted the color a bit... between say the 520 and the 830..as I've seen some that we not a total gray...but had just a slightly "olive" hue. Khaki? more than likely a repaint.

Subject: [TS-520_820_530_830] VFO-820 Question

A few months ago I bought a TS-820S "tech special" at a hamfest. I repaired the problems in it and then decided to look for a VFO-820 to go along with it.

I bought a nice looking one on eBay. It was obvious from the picture that it did not have the spinner knob, instead having the older style non-spinner knob. What was not obvious from the picture, was that the cabinet color was not the khaki color of my TS-820S and all the other hybrids that I've seen. This vfo is gray. This is not a repaint job by a previous owner unless he was an expert. Inside and out, this appears to be factory. Did Kenwood ever produce the VFO-820 in gray?

I'm not sure at this point whether to repaint the VFO-820 cabinet to match the TS-820S and maybe someday replace the knob with a spinner type or just sell this one and buy another one that already matches. I hate to change the color on it if in fact this is the original color.

Joe, you may be right...the trouble is, both units look like factory paint jobs yet they are definitely not the same color.

I thought maybe since this VFO-820 doesn't have a spinner knob, that it could maybe be an early version that was also painted different.

Alan,

I repainted numerous cabinets over the last few years. If the cabinet is not full of rust/corrosion, I clean it with a "scratchy pad" and some "simple green." This cleans well and is non-toxic/biodegradable. Also, it leaves the hammered/lumpy "factory look" to the paint. The "scratchy pad" will leave super-small scratches on the surface and also will take off what gloss is there. A light coat of gray auto primer, followed by the "color coat" will leave the case looking almost like "factory." There was a discussion about 3-4 weeks ago here regarding case painting. It was me wb7uqu, and Gordon n6wk and, another guy whom I can't remember right now. Good luck.....

Chris,

There is a guy on EBAY that sells spray cans of the correct color. He's in the US. I think it's about $15.00 USD a can. I have used some and it's correct color/gloss. I don't know about sending ORM-D stuff to NZ. If you have a good sample to go by..a good automotive paint shop can help. Also, any paint supply house...I don't know what you have "down there" can "computer match" the color/gloss...it just might be more than you want to spend. Good luck.....

Chris,
I bought some paint from the guy on ebay and I can tell you it does not match which becomes a problem if you have several pieces in your Kenwood rig. You are much better off to take a sample to a good auto paint shop. They have computers that read the color for an exact match and they can also put the paint in a "rattle can" for you which will cost less money than buying on ebay. They also have a additive that is mixed with the paint in varying amounts to "adjust" the finish from high gloss to flat. The auto paint shop is definitely the way to go. Hope this info is helpful.
Best regards,
Butch Lewis

Chris,

There is a guy on EBAY that sells spray cans of the correct color. He's in the US. I think it's about $15.00 USD a can. I have used some and it's correct color/gloss. I don't know about sending ORM-D stuff to NZ. If you have a good sample to go by..a good automotive paint shop can help. Also, any paint supply house...I don't know what you have "down there" can "computer match" the color/gloss...it just might be more than you want to spend. Good luck.....

Hi everyone, new to the group.

Is is possible to get spray paint cans that match the colour of the TS-830s and TS-930s still?
If so, any good sources? Of course, I would need to get them shipped to New Zealand.

Thank you
Chris Parnell, ZL1CDP

BTW if you go into an auto parts store and they happen to sell Dupli-Color or Plastikote brand you can get very very close. I did a TS440SAT that I had that was in perfect shape and the radio came out looking brand new.

It could also be that the 20 mtr het osc coil is adjusted incorrectly and the osc has "chirped out". Back the slug out to the top of the coil form then slowly turn it clockwise for a peak then back it off a bit as described in the manual.

Ken - KB7H

> > >
> > > The 20 meter heterodyne crystal is 22.895Mhz. If it is found to have failed completely, not due to dirty wafer switch contacts or any broken connections at the switch

or crystal leads, you can order a replacement from International Crystals in Oklahoma City, OK
> > >
> > > http://www.icmfg.com/hamradio.html
> > >
> > > They have an 800 toll free number you can call to place the order.
> > >
> > > Having said that, make sure the 22.895Mhz 20 meter HET crystal has, in fact, failed. You do not want to order a replacement to find out the problem was a dirty band switch wafer, broken wire/connection to the 20 meter wafer tab on the RF Unit and not an actual crystal failure. So make sure before you order.
> > >
> > > Typically, a replacement 22.895Mhz crystal will cost around $22 plus approximately $3 USPS shipping. You may have heard that International Crystals is charging "$50" or more for replacement crystals. This is true ONLY for crystals with frequencies of 5Mhz and below, not true for crystals with frequencies above 5Mhz.

Hi Chris,
I found a very close match in Supercheap Auto for my TS-520. Hard to tell from my other rigs. Or, go to a paint shop with the cabinet and they will match the colour and put it in a spray can for you. Last time I did this the cost was about $25.00, got to be cheaper than trying to get it from the US .It is unlikely that an airline will carry them from the States.
Cheers,
John

Good morning Ken,

I agree if the 20 meter heterodyne oscillator coil has been misaligned either by Dave or if Dave is not the original owner, by a previous owner. That is why my initial response stated that Dave should be absolutely sure the 20 meter het crystal is, in fact, the source of the problem and not something else such as broken wires, dirty wafer switch, etc.

> > > >
> > > > Having said that, make sure the 22.895Mhz 20 meter HET crystal has, in fact, failed. You do not want to order a replacement to find out the problem was a dirty band switch wafer, broken wire/connection to the 20 meter wafer tab on the RF Unit and not an actual crystal failure. So make sure before you order.
> > > >
> > > > Typically, a replacement 22.895Mhz crystal will cost around $22 plus approximately $3 USPS shipping. You may have heard that International Crystals is charging "$50" or more for replacement crystals. This is true ONLY for crystals with frequencies of 5Mhz and below, not true for crystals with frequencies above 5Mhz.

Subject: Re: [TS-520_820_530_830] VFO-820 Question

Joe, you may be right...the trouble is, both units look like factory paint
jobs yet they are definitely not the same color.

I thought maybe since this VFO-820 doesn't have a spinner knob, that it
could maybe be an early version that was also painted different.

Subject: [TS-520_820_530_830] VFO-820 Question

A few months ago I bought a TS-820S "tech special" at a hamfest. I repaired the problems in it and then decided to look for a VFO-820 to go along with it.

I bought a nice looking one on eBay. It was obvious from the picture that it did not have the spinner knob, instead having the older style non-spinner knob. What was not obvious from the picture, was that the cabinet color was not the khaki color of my TS-820S and all the other hybrids that I've seen. This vfo is gray. This is not a repaint job by a previous owner unless he was an expert. Inside and out, this appears to be factory. Did Kenwood ever produce the VFO-820 in gray?

I'm not sure at this point whether to repaint the VFO-820 cabinet to match the TS-820S and maybe someday replace the knob with a spinner type or just sell this one and buy another one that already matches. I hate to change the color on it if in fact this is the original color.

73,
Alan, KD5R

Thanks, Joe. I went back and read the posts that you referenced. After reading those and other posts, it seems that no one paint color is going to match all of the KW hybrids out there.

Actually, I like the "warm" look of the khaki color as opposed to the "cold" look of the gray. It looks right at home on the hybrid. To get them both exactly the same will probably require repainting them both. I'm not limited to the use of spray cans here as I have both high pressure and HVLP spray equipment. It would be nice to have an oven like Gordon has for drying the paint. If I used the XYL's oven, I would have more to worry about than the color of my cabinets!

Alan,

I repainted numerous cabinets over the last few years. If the cabinet is not full of rust/corrosion, I clean it with a "scratchy pad" and some "simple green." This cleans well and is non-toxic/biodegradable. Also, it leaves the hammered/lumpy "factory look" to the paint. The "scratchy pad" will leave super-small scratches on the surface and also will take off what gloss is there. A light coat of gray auto primer, followed by the "color coat" will leave the case looking almost like "factory." There was a discussion about 3-4 weeks ago here regarding case painting. It was me wb7uqu, and Gordon n6wk and, another guy whom I can't remember right now. Good luck.....

Thanks, Greg. For a while I thought maybe I was the only one with a khaki hybrid!

I was in Lowes a while back and noticed they carried Rust-oleum camouflage paint
in three different colors, one of which was khaki. I didn't have my 40# hybrid under
my arm for comparison, but it appeared to be a close match. It dries to a flat,
non-reflective
finish but after curing, one should be able to buff it out to a suitable gloss level. Maybe
I'll pick up a can of it to try on a test surface.

Hi Alan,

From my younger days when I painted several automobiles…. If the Lowe's paint is an enamel buffing after curing often causes enamels to dull, not gloss.
Stoll, you can try it, or spray a light coat of clear gloss on top after the color paint hardens for a week or so.

Lacquers are the opposite. Unless you bake the "crap" out of lacquer immediately after spraying, the formaldehyde evaporator in the thinner which hardens
The paint thru evaporation causes the laquer to go dull, requiring buffing to get the gloss. GM had a two step curing/baking process when they used lacquer.
The first oven was around 180 degrees, the second was over 300 degrees to re-melt the finish after the formaldehyde was gone. No buffing required.

FYI,

Greg

Topic: 29418 Message: 29418

I've been trying to figure out a low cost option for adding 6 meter SSB to my station when I set up my TS-830S soon. Right now I am thinking of a Ten Tec 1208 and then maybe a 6 meter amp to boost the output. Since the transverter only takes 5 watts max and the amp will turn that into 100 watts and not take more than that, how to I make sure not to overdrive both of these with the 830? I thought there was a low power switch on the 830, but, looking at the instruction manual, I don't see it. Any ideas?

Jon,
The TS-830S does NOT have a Calibrator Button. The TS-530 does.
The TS-830S has a DH button which freezes the display. The Calibrator
Switch is on the Mic control on the 830.
Turn it fully CCW until it Clicks, then the Calibrator is On

Mike,
Thanks you very much for that information :-) I feel so stupid not noticing that, and thinking it was the same as my TS530sp :-)
Things will be better in a fortnight when I get the cataracts lifted LOL
What exactly does that button do?
Kind regards
Jon

Jon,
The DH button stands for "Display Hold" so you know what frequency you
were on if you start tuning around.

29426. New Shack - grounding Kenwood hybrids question

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-21 01:09:30 UTC
From: silverstone38s
Topic: 29426 Message: 29426

When grounding the station, which at this point is AC powered equipment (Kenwood hybrids), antenna tuner, SWR meter, I have the following options and questions.

Points to consider when addressing my questions:

1 - I'm new to this, so fire away. Try to be nice, but I can take it either way!

2 - my plan is to only have the equipment plugged in during use - I'll disconnect the surge protected power strip, when I'm not in the shack. My VFO will most likely be an analog and I don't believe other units, will have issue with being unplugged when not in use.

3 - My antenna will be indoors (an attic dipole). I'll just be putzing around on 40 meters, until I figure out what the heck I'm doing! Obviously, this could change in time and I would have to address lightning at that point.

Ok, so:

1 - I have a surge protected power strip connected to a grounded AC outlet. Ground was tested and the power strip indicates good ground as well (for what that's worth). Assuming it is correctly grounded, is this sufficient ground?

2 - My shack is a converted dining room, shared with the Mrs as a Study, so we have computers, etc., and it's presentable, carpeted, etc. I could drill a small hole in the floor, against the wall, and connect to a cold water pipe in the basement for ground. This is probably the shortest distance to ground (less than a few feet I would guess).

3 - Just outside the window of my shack, an outlet for our above ground pool filter was installed by an electricion. That outlet is grounded and I wonder about tapping into that with 8 gauge wire. Could be an option, but does involve getting the wire through the wall/window. Distance is maybe 10 to 12 feet.

4 - My electrical meter is about 30 feet from my operating station, but I could tie directly to the box. Still, that is 30 feet away.

Anyway,thanks for any suggestions.

29427. TS-830s No audio

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-21 03:02:29 UTC
From: John
Topic: 29427 Message: 29427

Recently purchased a TS-830s that seems to have a receive audio
problem. I can tune to WWV and watch the S Meter pulse in time to
the time signal pulses. And tune away from it and watch the s meter
drop. So, I know it's receiving wwv, but, no audio output. I checked
the Phone jack on the front as well as the external speaker out jack
and the internal speaker. All seems to be working fine. Just won't
pass no audio. I am wondering if Q4 or Q5 might be the culprit?
The guy I got the radio from told me he hooked it up once and there was
audio out from the internal speaker. (I bought the radio as a fixer upper so I don't hold
the no audio problem against him.)
The Calibration signal doesn't work either.
I did find one wire that was cut in two and taped back together, although no connection
between the two halves !! I re-soldered that
and put heat shrink on it but, that was not the problem.
Any ideas would be greatly appreciated.
james

Topic: 29375 Message: 29429

This one came off of e-bay, and was listed as an item needing work. As far as I can tell, I am the third owner of this radio. I know everything about the original owner, as the rig came with all the purchase documents, and couple of factory service invoices, the original QST review, and some other fascinating stuff. The second owner I don't know much about, as he didn't seem to really know much about radio. I suspect, but can't prove, it was an estate sale item.

Thanks for the info.

problem. Also check wiring to the switch wafer to ensure there are no broken wires.
> > >
> > > The above test is easy to do, all you need is a simple RF signal generator. I recommend using a .01ufd 50VDC or .1ufd 50VDC disc capacitor between TP3 and the signal generators' output. This will isolate the generator, "DC wise", from TP3, preventing any DC voltage from being applied to TP3. All you want at TP3 is an RF signal from the generator, no DC voltage.

Thanks. I was taking a break from the manual and my electronics manual, figuring I'd look to see where the shack fits best in my house. I hadn't gotten to the point on grounding for RF. Fine! I'll get back to reading...

I do get the bus strategy and that has me thinking now about where to place my shack.

I remember simpler Novice days in the 60s when my shack was in the attic and I ran a wire from the back of the Heath DX-20 to the galvanized cold water pipe for a chassis safety ground. Back then I didnt know there was such a thing as an RF ground! Somehow was able to make numerous contacts and had best fun as a ham.

This topic could generate days of myth, misconception and magic on this forum. Probably not right place for this so I apologize, but do sympathize with the beginner. Suggest you go to www.dxzone.com and type in ham station grounding and you will find many good articles on Safety and Surge Protection and Lightning and RF Grounds. Focus on Safety first and then worry about ensuring less than 1/4 wavelength ground cable on highest operating frequency and Ground Loops and RFI and Bonding and Ground Rod cages and ....!

There are conflicting opinions on the bus strategy vs. grounding to one point. Keep researching and make your own decision.

I recommend reading W8JIs' webpage on grounding. This will explain quite a bit about safety, lightning, and RF grounds.

I'll accept that you can't get the 830S down to five watts to drive a TenTec 1208 transverter . . . . but I have one other question, then. What would you be able to use to drive one of these? Even the old Heathkits put out 100 watts, so what do you use?

The transverter output on the TS-830S is probably less then 1 watt.

The kenwood hybrids have a switch on the back that shuts down the final and a low power output to drive thier transverters.

820
Well I took it back off the shelf to see what I could see. I need to find out what kind of issues I would be halving with the 820 IF.... the band switch coupling between the driver stage and the final band switch was not snug or turning the back set of wafers in the final cage? This rig has a white plastic coupler that has let go. All the front wafers of the band switch turn snug and smooth with the front control knob. However the wafers behind the white coupler in the final section do not turn at all.

I can transmit and receive across the room to another rig. It works on upper and lower ssb as well as cw. When I tune it for max output there is no rf output via the meter however as I adjust the driver the output can be peeked using the receiver of the other rig. All audio functions work. Vox, Mic gain Speech Processor etc all work. The CAR control on the front panel also adjusts the output of the driver adjustment and can be seen on the other receiver when it is adjusted.

I tried to find what band it was on when the band switch let go and stopped adjusting the band switch in the final cage. I tried all bands and can not find any band that will tune with any output? I guess it could be on AUX position with out a crystal?

Where can I get a replacement coupler? Gordon N6WK if you have one I could stop by and pick it up and shake your hand again. Then you could give me some tips on the easiest way to get to it. From what I see it looks like you need to take just about everything out of the Final RF cage to get to it and reset the wafer?

I also need the front panel plastic toggle switch that slides onto the Send, VOX, NB, MONI switches. The tabs have broken off and a couple of the switches are hanging there by the skin of there teeth.All the switches work fine but the plastic front has broken.

If the final amplifier band switch wafer coupler is broken then the final amplifier band switch wafer will be out of sync with the other band switch wafers resulting in the symptoms you are experiencing.

Replacement couplers can be obtained from Ken (K4EAA)

www.k4eaa.com

Check Kens' website for further details.

For replacement switches, check with Bob Mansker, ke5ftf at mail.com.

The AUX band switch position is for receive only, no transmit.

The TS-830 has a rear panel Xverter DIN socket. The Xverter DIN socket pin functions are shown in the TS-830S operators' manual on page 13. You can also trace the 830s' internal wiring to the X verter DIN socket, to determine what each pin is connected to and what each pin controls inside the 830, using the high resolution 830 schematic available at Gordons website

www.n6wk.com/kenwood/

If you go to Gordon's site (N6WK), in the Kenwood hybrid files section, open the TS-820 service manual. On page 37, figure 18 may provide some insight on removal/installation of the stand by/paddle switch. Be very careful, they are easy to break. If you break it Bob Mansker should have some replacements.

hi Roy,

I have a ts-530 and used the QRP circuit
to reduce power out.

it usees 9v battery and a trim pot to
feed -9v to the alc in pin and ground
on the remote DIN on the rear of the radio.

You need a 270 deg DIN male.

Look in files section for qrp you
will find schematic.

Sorry for the delay, Joe. I've been busy with an RFI problem and the utility company, a TS-940 that started acting goofy the other day, and a sick dog. When the dust settles around here, I do intend to go over the alignment steps per the manual.

Hi All
My 20 m dipole fell during the recent Massachusetts snow storms and is buried under the snow with no chance of raising it back up until spring. I have been licensed for a year running 100w in a 520se and having a blast.
What is the quickest way to to get back on the air using some sort of antenna that doesn't require standing in the freezing weather for an extended period of time. I have heard of some hams just running wires out the second floor window and tuning it up or using "bed frames" and a tuner to get back on the air. Due to a medical condition the easiest the better.
I have a tuner but don't have any experience using it but will certainly use it if needed. The 20 m dipole did not require it.
Any help would be appreciated.
Once spring shows up I will install a 40/20/10 multiband dipole.

Hello Fred,

My "backup" antenna is a homebrew, multi-band vertical. It is EXTREMELY versatile and weatherproof, with great performance. It is actually less noisy on receive and will give your 100 W signal about 1 S-unit less performance on the receiving transceiver.

If you don't want to homebrew, buy this antenna. It goes up in about 15 minutes and will have excellent performance. You can't beat the price and you'll have it for a long time as your "backup".

Thank You for all the reply's. I really love this 820 and miss it on the desk. So Ken I will get a hold of you later in the week to see if the couplers are in and we can set up a convenient time for you, so I can stop by and pick one up.

I am trying to remember if the last time I had the rig on and working if I changed the band switch to WWV? If the back part of the band switch got stuck on WWV then it would make sense that none of the bands would tune at all. Who knows. I have a hard time remembering the simple things from day to day.

The thing that is the bugger is that I was looking for electronic parts/component failure on and off for hours. Testing voltage, pin connection, relays, etc. I found nothing that made any sense. The back set of band wafer switches are tucked in behind and under a bunch of other components and with my old eyes looking in the rig you can not see the switch easily.I took a high intensity flash light and started to look for anything at all that did not look right. cold solder connections, broken or melted wires, etc.

I should have looked at the band switch much sooner and saved many hours of looking. Now that I have taken and cleaned just about every plug switch and connection on the unit I have the worry that I created more issues with the rig than I fixed. I will let you know if the band wafer alignment and coupler repair takes care of all my operation issues.

And thank you for the toggle switch replacement information. At least I don't have to take the entire front panel off this 820 to pop on a new toggle on the switch.

Everyone have a great weekend.
Best Wishes

Topic: 29458 Message: 29458

Hi All,
I've owned a TS-820S since the mid 80s and its been in storage for 20 years. Recently I've had the bug to get this rig back on the air so I got it out of the mothballs and powered it up. It sounded really bad and was not as sensitive as it use to be. It also had an AC hum on the audio, the electrolytics have dried out and/or changed capacitance.

For the past week I've been replacing all of the Electrolytic capacitors. While I was under the hood I cleaned all of the connectors and switches. Well I got the radio completed making sure all the cables were connected properly and well seated then I flipped on the power switch, no explosions or smoke. Tuning around it wouldn't receive anything, just a bunch of hissing. I took the boards back out and checked the polarity of each replaced cap. Everything was good, holy cow I ruined my radio, I turned it into a piece of wood.

In the rebuild process I had to flip the radio around alot to get to the boards. Well I also flipped the the 6m xverter switch on the back of the radio to the "ON" position. Doing so routes the anntena signal through a converter if I had one. This morning I noticed the position of the switch and turned it OFF and the radio came to life. What a good feeling.

Everything works great, the small hum I use to have is gone and the receiver is much more sensitive, signals are coming in like gang busters. I have yet to try the transmitter. For that I will bring it to a friends house because I don't have my antenna up yet, spring project.

The last thing to do is construct a new cable to connect my VFO-820 to the rig.

For those of you needing to perform repairs on the TS-820S, use a good temperature controled soldering pencil dialed to about 650F or just enough to melt the solder. The foil on the boards will come up very easily, I had to repair one pad when I used ~700F temp. I also cleaned the pads with 91% Isopropyl Alcohol before de-soldering, that helped alot.

Gordon
Thank You, do you think it is better to replace the coupler with the original part? Or is the brass stronger and more durable? Once I put the new coupler in I would prefer not to have to replace it again. If the metal or brass coupler is a little stronger and is a more permanent fix than that would be better. I will drop Bob Mansker a note and ask him if he has any plastic paddles for the switch replacement.
Thanks Again

Bob,

The brass couplers from Gordon (via k4eaa) are great. They are brass, very
well machined, and have 4 set screws. The only problem you might have is finding
a long enough "allen" type wrench to get all the way in. I have replaced
...oh...maybe about 25...so far. The plastic ones were fine for awhile...but
screws and nylon in a tension/rotational setting...most times just don't mix!
Use the brass...you won't have to worry about it again. Good
luck.................

Topic: 29465 Message: 29465

I am still a little confused . . . . I understand using the transverter connections on the back of the TS-830S. I took a look at the instructions for the Kenwood TV-506 and it outputs 8 watts, but there's no mention of what the input is. The TenTec 1208 takes a 5 watt input and will output 8 watts. Does the TS-830S really only put out 1 watt through the transverter output? If I used the 1208, that would only give me about 3 watts, right?

Does anybody have any experience connecting a 1208 to the TS-830S?

Gordon
Is there any issue with the metal or brass not isolating the drive from the final sections of the rig?

the FT101zd has a 1 watt (or less) output socket for transverters. My old FTdx401 had a half watt output socket. Great for QRP fun with locals :-)

GROUP,

In regards to the correct size "allen type" wrenches.. I forgot to mention in the prior post....I bought a complete set from on-line "hobby store." It was a complete set of 7. On KW's you'll only use 2.....on my motorcycle I can use 3 others..... but they were inexpensive, good quality...and cheaper and longer than ones I tried to find at Lowe's/Home Depot. They have shafts about 3.5" long and are color coded. They will fit the small "allen type" screw on the factory coupler(s) and also...the later model rig using the "allen type" screws on the knobs up front. Or you could check with your local hobby store/shop.....good luck

You can find an extra long L wrench at Home Depot or stop a Snap On truck he'll sell you one ...

Bob,

The brass couplers from Gordon (via k4eaa) are great. They are brass, very well machined, and have 4 set screws. The only problem you might have is finding

a long enough "allen" type wrench to get all the way in. I have replaced ...oh...maybe about 25...so far. The plastic ones were fine for awhile...but screws and nylon in a tension/rotational setting...most times just don't mix! Use the brass...you won't have to worry about it again. Good luck.................

Ken K4EEA sells the shaft couplers...check his site under "parts." Ask him about the toggle switches too. He doesn't advertise them, but I'd be willing to bet he has a couple available.

In regard to no RF output indication, check the RF volt potentiometer on the back panel and adjust it for 2/3 scale reading w/ the meter switch in RF. It's not a calibrated function and is only supposed to provide a relative indication of output.

> Well I took it back off the shelf to see what I could see. I need to find out what kind of issues I would be halving with the 820 IF.... the band switch coupling between the driver stage and the final band switch was not snug or turning the back set of wafers in the final cage? This rig has a white plastic coupler that has let go. All the front wafers of the band switch turn snug and smooth with the front control knob. However the wafers behind the white coupler in the final section do not turn at all.
>
> I can transmit and receive across the room to another rig. It works on upper and lower ssb as well as cw. When I tune it for max output there is no rf output via the meter however as I adjust the driver the output can be peeked using the receiver of the other rig. All audio functions work. Vox, Mic gain Speech Processor etc all work. The CAR control on the front panel also adjusts the output of the driver adjustment and can be seen on the other receiver when it is adjusted.
>
> I tried to find what band it was on when the band switch let go and stopped adjusting the band switch in the final cage. I tried all bands and can not find any band that will tune with any output? I guess it could be on AUX position with out a crystal?
>
> Where can I get a replacement coupler? Gordon N6WK if you have one I could stop by and pick it up and shake your hand again. Then you could give me some tips on the easiest way to get to it. From what I see it looks like you need to take just about everything out of the Final RF cage to get to it and reset the wafer?

Somewhere I read, maybe on the Ten Tec site, you can diddle with some resistor(s) on the input side of the 1208 so that 1/2 watt will drive the 1208 to full output. When in doubt, give Ten Tec a call or drop them an e-mail with your questions. Here you might get a dozen different answers. Go to the source.

Just found this on the internet for the 1208 so it must be correct: "However with a simple resistor change your input can vary between a 1/2w and 10watts input".

I use my TS-830S to drive a SSB Electronics 6 meter transverter which takes about 1/2 watt to drive it. Works great.

Hello to all,

please remember it is a transverter not an amplifier.
The output of the rig is brought down to milliwatts
or less than mixed up and amplified again.
If your input from shortwave side is to high you
kill your transverter nothing else.Your output will
not be higher.

29473. Basket-Case TS-530S Restoration

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-23 20:36:11 UTC

Hello,

Can anyone here reccomend a good repair shop that would be interested in working on a TS-530S that I rescued from someones garage? Supposedly, the bandswitch coupler broke and caused some damage. It has been sitting in a garage for a long time. It appears to be complete, and the face should clean up nicely. The covers also need painting. When I turn it on, the digital display does come on, but the freq readout doesnt change when you spin the dial knob. I was also given several 6146 tubes that test good with the radio. This radio needs major work like K4EAA does, but he doesnt seem to be answering e-mails right now. I was given this radio for free, so I think its worth spending 2 or three hundred dollars to bring back to life.

Check to see if the VFO cables got unplugged. If there was some damage inside it would be easy for them to get loosened. It does not take much.

Good Luck!

kd8hmo,

I do know that Ken/k4eaa is real busy...and if you do contact him..he will give you a "send it to me date" which right now is probably around May+ . I can recommend two guys that have done work for me in the past. "GOOGLE" AVVid - Clif Holland, he's in Texas. Another one..he is quite good, through, and inexpensive is "Affordable Radio Repair".... Mike/N0BXE he's in Colorado.

God luck & 73's

Hello,

Can anyone here reccomend a good repair shop that would be interested in working on a TS-530S that I rescued from someones garage? Supposedly, the bandswitch coupler broke and caused some damage. It has been sitting in a garage for a long time. It appears to be complete, and the face should clean up nicely. The covers also need painting. When I turn it on, the digital display does come on, but the freq readout doesnt change when you spin the dial knob. I was also given several 6146 tubes that test good with the radio. This radio needs major work like K4EAA does, but he doesnt seem to be answering e-mails right now. I was given this radio for free, so I think its worth spending 2 or three hundred dollars to bring back to life.

Greetings Group!

Well..thought I was done fixin' a "CB" hack job on an 820(s)..got the PLL/PD unit replaced with spare from parts bin. Other things should have indicated to me something else was wrong, Someone had put in 2 watt carbon.comp "R's" on the final board for the cathodes, these were burned/discolored. Replace with correct value/wattage metal film as were the screen "R's."

Well to make it short. Fired it up..good.... no smoke..then "tuned-up" on 20 meters..50W @ 200mA..well turned up "CAR" control..it went to 100W..but "Ip" went to 300mA+ and "pop - pop." There goes the new cathode "R's." Took a look around and found something odd. One of the wires from the "final board" PD2 terminal was changed from the "210" terminal on the "HV" board to the "300B" terminal on the rectifier board. Was this some kind of "QRO" mod? I have not completed the repair...so I don't know if all is well..yet...

Terry,

Thanks for the message, it reminded me to post the results
I had in getting in touch with Ken.

Here are a few notes from our conversation;

As Terry mentioned, Ken is just plain out of storage room.
If you anticipate sending a rig to him, call first, this will put you into his que. At that time he will give you a date to send the rig. IOW, you store the rig until he's ready for it.

When you ship the rig, send him an email and he will respond with an approx. completion date. He said right now the completion dates are about 2 weeks from receipt of rig, if he wants your rig earlier than that he will contact you.

Be sure to fill out the form on his web site with all the pertanant info. He said you would be suprised at the number of radios he receives without ANY info on the boxes. He has rigs right now and he has no idea who owns them !!!

I remember, I think it was last year, that he was contimplating hiring some help so I asked him about that and he simply said that didn't work out, so it's just he and his wife.

We had a great conversation about some of our common interests, he is a super guy.

Tom
W4TMW

ps; to give you an idea of the backlog, my ship date to him is mid-May.

Topic: 29489 Message: 29489

Greetings Group,

Well..finally got the "hack" job fixed, thanks to a spare PLL unit. Another thing I found...AFTER I popped the new cathode "R's".. was that the/a prior owner along the the crystal change, moved the PD2 wire from the HV board 210 post to the rectifier board 300B post...no wonder there was 300+mA Ip on the finals before they popped the cathode "R's." All is now fixed and workin' as it should...Now onto that 520 with no audio...

From: w5rkl
Topic: 29489 Message: 29490

If the wire from HV "210" wire was moved to the Rectifier Units' 300B terminal, the final tube screen voltage would be approximately 350VDC in standby, slightly lower in transmit. The typical final tube screen voltage is 255VDC in standby and 210VDC in transmit.

Increasing the screen voltage to 350VDC easily exceeds the 6146B maximum screen (Grid #2) voltage of 250VDC by "100VDC". While the person who thought this would be a good idea, it's quite obvious he/she did not pay attention to the 6146Bs maximum grid #2 levels.

I recently bought a VFO for an 830 from this gentleman. His communications were quick, his responses positive, his description accurate, his prices reasonable, and his shipping very well done.

My experience may vary from some others, though I have heard nothing bad, and I would not hesitate to buy from him again.

Those of you that have purchased the Taylor 6146B's from RF Parts, how good have they been as far as life expectancy? I wonder how good those tubes, as well as other today's brands are compared to the RCA, GE, etc that was made "back in the day" when they were manufactured for transmitting as well as consumer equipment that didn't require as high of voltage ratings as transmitting tubes did.....John

29501. external vfo plug on ts-520s

Topic: 29501 Message: 29503

Tom,

The internal VFO operates from "9VDC". There is one wire that goes to pin "9" on the rear panel VFO socket that has "9VDC" on it. The 9VDC is present on this wire when the Function switch is in the following positions

VFO
25Khz
RMT
FIX

With the 520 turned OFF, pull the 2 pin plug from the rear of the VFO. The "large" pin is the power pin for the VFO. The smaller pin is the "RIT" pin.

Make sure none of the wires are shorting together and none touching the chassis or rear panel.

Set the Function switch to "VFO".

Connect an ohm meter lead to the large pin and the other lead to each wire from the remote VFO socket. One of the wires will show continuity. When found mark this wire as pin "8".

Connect a DC voltage meter set to measure 20VDC. Connect the black negative meter lead to the chassis. Power up the 520 and connect the other volt meter lead to each remaining wire until the volt meter displays "9VDC". This wire is the VFOs 9VDC source voltage. To be sure you have the right wire, switch the Function switch to "VFO R", the meter should no longer display 9VDC but rather close to zero VDC. Set the Function switch back to VFO and the volt meter should display 9VDC again. Mark this wire pin "9".

The shielded wire is the VFO's Output. Mark the shield as pin "2" and the center conductor as pin "1".

With the 520 still powered up, leave the voltage meter negative lead connected to the chassis and touch the other lead to the other wires until you find 12VAC. Notice I said "AC" and NOT "DC". Once you find that wire mark that wire as pin "4".

Set the Function switch to "RMT" and touch the other wires until you the volt meter reads "9VDC". To be sure you have the right wire, move the Function switch to FIX and the volt meter should display zero VDC. Rotate the Function switch to RMT and the volt meter should display 9VDC. Mark this wire as pin "6".

At this point you should have only 1 wire left that is unmarked and untested. Mark this wire as pin "5". This wire is the remote VFOs "relay" voltage and is only energized when the 520 is placed in transmit. The voltage is approximately 12VDC to 14VDC, again, ONLY when the 520 is energized and switched to transmit.

Pin 3 of the 9 pin remote VFO socket is "ground".

Pin 7 of the 9 pin remote VFO socket is "open", nothing connected.

You can order a replacement 9 pin socket from Radio Daze

www.radiodaze.com

The new socket will have the pins numbered on the terminal side of the socket. Look closely when you make wire connections to the socket to ensure the correct wires are connected to the correct socket terminals.

Once you get the new 9 pin socket wired correctly, mount the socket so the wider space between the pins is at "6 o'clock".

Check your wiring against the 520s' schematic.

Make sure the 2 prong plug is inserted into the rear of the internal VFO and the RCA plug is fully seated/inserted into the RCA socket on the rear of the internal VFO. The 2 prong plug will only go in "one way" so don't try to force it.

To operate the 520 without the external VFO, a jumper wire must be connected between pins "8" and "9". This jumper provide power to the internal VFO.

Hi,

GE JAN USA circa 1985 new in box $18 each,
no need for 'matched pair' in our kenwoods.
GE Driver 12BY7A also available $10

http://www.surplussales.com/Tubes-Sock-Acc/TubeSpecials.html

I believe the Taylor tubes are made in China at RF Parts.

I called RF Parts several months ago and spoke to them about 6146W's. They told me the Phillips/ECG are OK in Kenwoods, the GS 6146W isn't.
Also, their Taylor 6146B's are "screened and tested" Chinese 6146B's.

FYI,

Greg

Tom,

The internal VFO operates from "9VDC". There is one wire that goes to pin "9" on the rear panel VFO socket that has "9VDC" on it. The 9VDC is present on this wire when the Function switch is in the following positions

VFO
25Khz
RMT
FIX

With the 520 turned OFF, pull the 2 pin plug from the rear of the VFO. The "large" pin is the power pin for the VFO. The smaller pin is the "RIT" pin.

Make sure none of the wires are shorting together and none touching the chassis or rear panel.

Set the Function switch to "VFO".

Connect an ohm meter lead to the large pin and the other lead to each wire from the remote VFO socket. One of the wires will show continuity. When found mark this wire as pin "8".

Connect a DC voltage meter set to measure 20VDC. Connect the black negative meter lead to the chassis. Power up the 520 and connect the other volt meter lead to each remaining wire until the volt meter displays "9VDC". This wire is the VFOs 9VDC source voltage. To be sure you have the right wire, switch the Function switch to "VFO R", the meter should no longer display 9VDC but rather close to zero VDC. Set the Function switch back to VFO and the volt meter should display 9VDC again. Mark this wire pin "9".

The shielded wire is the VFO's Output. Mark the shield as pin "2" and the center conductor as pin "1".

With the 520 still powered up, leave the voltage meter negative lead connected to the chassis and touch the other lead to the other wires until you find 12VAC. Notice I said "AC" and NOT "DC". Once you find that wire mark that wire as pin

"4".

Set the Function switch to "RMT" and touch the other wires until you the volt meter reads "9VDC". To be sure you have the right wire, move the Function switch to FIX and the volt meter should display zero VDC. Rotate the Function switch to RMT and the volt meter should display 9VDC. Mark this wire as pin "6".

At this point you should have only 1 wire left that is unmarked and untested. Mark this wire as pin "5". This wire is the remote VFOs "relay" voltage and is only energized when the 520 is placed in transmit. The voltage is approximately 12VDC to 14VDC, again, ONLY when the 520 is energized and switched to transmit.

Pin 3 of the 9 pin remote VFO socket is "ground".

Pin 7 of the 9 pin remote VFO socket is "open", nothing connected.

I decided it was time to replace the tubes in an old TS-820 I purchased last year. It had been in storage for a number of years and required cleaning and some DeoxIT applied to the switches... It has been working fairly well for several months but always had some jitters in the drive current. I decided after reading the Kenwood service bulletins and knowing nothing about the age or history of the tubes to purchase replacements. They came today and I installed them. Within a few seconds of turning the heater on I saw a flash in the cage and heard a noticeable pop. There is nothing visually obvious to identify but the cathode resistors now read 4 ohms and .7 ohms. So I guess my question is are the tubes the cause or just a coincidence? I did not hit the send switch... just turned on the heater. very strange to me.
Anyone ever have a similar experience?
Jim KD8UT

You probably also need to replace the cathode resistors....
DON'T put higher wattage resistors in to replace them, they also act as fuses as spec'd.

Greg

Hi Ken,
I agree... if it ain't broke don't fix it! I have had a problem with grid drive and alc readings being a bit jittery since I received this radio. A 1977 Service Bulletin indicted that this could be caused by a bad 6146. Given my lack of history with the radio I didn't think new tubes could hurt anything and it might correct a problem... I WAS WRONG! It just created more problems. Oh well, that's what makes life interesting. Thanks for your observation. It is probably good advice.

29516. Re: [TS-520_820_530_830] Re: TS-820 Final Flash and Pop CO2KK recommends procedures to save tubes

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-27 01:24:35 UTC
From: Prof. Arnaldo Coro Antich
Topic: 29508 Message: 29516

Hi amigos !

My long time experience with broadcast equipment that used vacuum tubes led to the following
procedures to be adopted:
NEVER change a tube before the parameters have not changed below the 75 to 80 percent mark !

Keep the filament contacts clean (bad filament contacts may lead to low output and even
be the cause of a short tube life)

Handle glass tubes very carefully... don't remove them from the sockets when they are still hot !

Avoid excessive handling of the tubes when they are removed for purposes such as cleaning the
transmitter, checking the state of the sockets .

Measure the filament voltage right at the tubes pins of connectors, and be sure that it is within
the allowed tolerances

In the case of tetrodes and pentodes power tubes, it is extremely important to check the screen
grid voltages and also the state of the bypass capacitors connected to those tube electrodes

Periodically check the overload protection circuits for the plate current , and also for the
screen current in tetrodes and pentodes.

If a tube produces an instantaneous flashover , remove it from service ASAP, and don't use
it again. A tube flashing between screen and plate, for example, can cause a lot of damage if
the short circuit created by the flashover results in permanent short circuit paths !

Keep a record of the dates when the tubes are installed, and if possible, keep also a record
of the number of hours that it is in service.

In general it is NOT a good idea to keep power tubes with just filament voltage applied for
long periods of time... If you have to keep a transmitter in standby

mode, keep at least
a third of the total high voltage applied to the plate, and keep the
screen at ground potential.

Monitoring the filament voltage, and if possible regulating it to plus
or minus 5 percent
is extremely important to prolong the life of high power tubes !

Maybe some other list participants will add some more recommendations to
optimize
the care of the wonderful electronic devices that we know as vacuum
tubes in the Americas
and valves in Europe !!!

Welcome to the group. I have had the original tubes in a Kenwood T599 last until just this last year. So that was close to 35 years? They went south only because a rubber belt split and the tune and load was not tuning and loading so the the transmitter was not correctly tuned for the band change that took place. If the rubber belt had not broken I am sure the tubes would still be in there working to this day. So It all depends on the operation set up. Desk layout, cooling space of the equipment and of course the tuning of the equipment running it into a resonant antenna. Keying the radio only when it it connected to an antenna and so on. If it isn't broken leave it alone and enjoy it.

Jim,

If I remember right the "cathode" resistors on the 820(S) are 10 ohms each...and in parallel ...so they should measure about 5 ohms to ground...and not more than about 5.7 ohms. As Greg stated...DO NOT use higher wattage resistors! I use metal film replacements. The screens are 100 ohms each.. check those also. REMEMBER..if plan on working in that area make sure ALL the high voltage is gone...or you might end up as an SK... good luck

You probably also need to replace the cathode resistors....
DON'T put higher wattage resistors in to replace them, they also act as fuses as spec'd.

Greg

Your new tubes Flashed over. Are they the Chinese ones?
You need to send them back to the seller.

Loren,

Welcome to the group. As Bob stated, origninal tubes can and do last a long time. I have an 820S with the original S2001's...still going strong. Keep your "tune-up time" short. Take a look at K4EAA's web site..some good stuff if you are new/newer to "tube" type finals. A good thing to watch is..after your all tuned up...key down..and see if the Ip (plate current) goes up...then starts to drop..usually a sign that the finals are getting tired. Make sure meter switch is set to "IP" Usually testing these types of tubes in a tube tester is unreliable..unless it can test them for RF output. I have seen tubes that test good in the tester...but hardly worked in actual use. Good luck......

I have a quick filter question....

I have a TS-820S with a YG-88C CW filter and want to know if I can use it in my TS-830S.

Thanks

hi Greg,

Perhaps they are going by the tube specs to make that conclusion?
I prefer to use a US made tube over a China import give the
trouble they have caused members of this group due to defects.

http://www.nj7p.org/Tube4.php?tube=6146

http://www.nj7p.org/Tube4.php?tube=6146b

http://www.nj7p.org/Tube4.php?tube=6146w

I use the 6146W circa 1985 GE JAN in my 520 and 530.

hi Greg,

I also thought the cathode resistors were for fusing from reading about them on K4EAA website http://www.k4eaa.com/supersize.htm

Turns out the resistors are bypassed for RF, and are used for metering the cathode current. They have no other function.

There is a long discussion about the cathode resistors on Eham.net

http://www.eham.net/ehamforum/smf/index.php/topic,44291.0.html

29523. 6883B (12 volt filament conversion)

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-27 15:48:06 UTC
From: wagstw46
Topic: 29523 Message: 29523

With the recent finals discussion it reminded me that I have couple of NOS sets of 6883B finals. I have looked at the TS-830s schematic and it looks like a very easy mod for 12 volt filament operations.

My question: Is there any need to change or add any additional bypass capacitors?

I am currently running a pair of 6146Ws purchased from RF Parts and no real operational issues to warrant the mod. At my age with proper operation probably last another 30 years. I guess I just need a winter project and hate to let the 6883s end up in my SK estate sale!

Thanks
Terry-K9TW

Terry

The 6883 B is a 12 volt replacement for the 6146 in a final application. But what really would be fun is to use them to build a class B Modulator for use on AM. They would be great to drive a modulation transformer. There just are not enough on 3870 operating AM.

Bob- I ran AM years ago as teenager with DX-100 and later with Apache until I could afford SB-10 adapter. Today the modulation transformers would be the bigger expense and at my current QTH no room for dipole on 80. I guess I could put up random wire and use a tuner. Something to think about.

If it works, never mind.
I never, never understand some people that change everything because some other fellow who has even less experience, says so, be it tubes, condensers and more. It is very normal that a 30-40 year old set has some issues, mostly bad contacts in connectors, switches, relays and print boards.

DON'T FIX IT WHEN IT IS NOT BROKEN.

My experience in 50 years of hamming and repairing: Most problems occur when good sets are mishandled by people who don't know how things work in the first place.
That kind of sets are landing all the time on my workbench with all kinds of obscure man-made problems AND I AM TIRED OF IT.

Take haert OM, I have seen them far worse, and after some elbow grease and replacing some components you can not believe it is the same set.
I find it even more rewarding to fix such a set, than buying new.....

You are right: I was in the seventies yust as you drooling when I saw ads of the fine pieces of equipment, that were way out of reach.
That is why I love this older sets now, and the fine thing is that it now will not cost you an arm or a leg to have them.

Good luck with the resurrection of your basket case.

PGA, I'm glad you were able to save the old Kenwood.

I remember in my younger days of Ham Radio I would get a catalog from Longs Electronics, a folded paper catalog with maybe 50 pages, featuring the 520s 820s 530s and 830s on the front page. I always told myself I hoped someday I could afford at least the 520s. You know what.....I'm still thinking that same thing and that was in about the 1970s.

A little elbow grease will help make a world of difference in cosmetic appearance .

Some careful time spent cleaning the inside will resolve some of the issues . But it really does need to be a very thorough cleaning with the proper electronic cleaners and lubricants , as well as proper chemicals or pads etc. Don't take any shortcuts .

It looks much better than many rigs that I have brought back to life . Just a lot of time and patience .

Take a LOT of photos BEFORE you begin . They can be extremely useful , even if you have a lot of experience and especially if you are not extremely well versed in servicing to a component level this particular model , a TS-530S .

If you know you are at a point that you are getting in over your head , STOP and post to the list here . There are people that know these radios both inside and out , even without looking in the manual .

Keep us posted on your progress and a picture update in your step by step approach could prove useful to someone in the future .

Best wishes on your endeavor .

Charlie , W5COV

Hi Loren,

No it's not a problem. You can turn main power OFF but leave the Heater switch ON. Now don't be confused into believing that if main power is OFF but the Heater switch is ON means the driver and both final tube filaments are still ON because that's not true. The main power switch control the AC power applied to the radio. The Heater switch simply controls the driver and both final tubes filament voltage from the 12VAC secondary filament winding on the power transformer.

Is it possible that 530 was in a flood? If that is the case the owner would have
no control over the 530s current condition.

Just a thought.

Hi Loren,

No it's not a problem. You can turn main power OFF but leave the Heater switch ON. Now don't be confused into believing that if main power is OFF but the Heater switch is ON means the driver and both final tube filaments are still ON because that's not true. The main power switch control the AC power applied to the radio. The Heater switch simply controls the driver and both final tubes filament voltage from the 12VAC secondary filament winding on the power transformer.

The final amplifier plate choke can be rewound with new enamel wire. I don't recall what the wire gauge is.

If you do not feel like rewinding the choke you might be able to find a replacement from Bob Mansker KE5FTF. Bob has a big collection of TS-520 to TS-830 rigs. Drop him an e-mail at ke5ftf at mail.com. He also may have other parts you may need. Make sure you tell him the RF choke is the single layer choke, same as the one in your radio. Send him a picture of the choke.

One additional comment.

In receive the transmit circuits that are not associated with receive, are biased to cut off (turned OFF), even the driver and both final tubes. In receive the driver and both final tubes do not conduct, only the filaments are glowing/lit, no current flowing in the tubes.

There are a few "common" circuits, circuits that work in both transmit and receive such as the VFO, carrier generator oscillator, IF stages, and power supplies. Those circuits will remain on but none of them are not controlled by the Heater switch. As I said earlier the only thing the heater switch controls is the driver and both final tubes filament voltage, nothing more.

I would not recommend leaving the radio on 24/7 365 days a year but letting it be powered on and sit idling during the day while you do other things will not harm the radio.

When I first got into the two way radio repair business in 1971, a lot of customer base stations still used 6146 tubes. The base stations were on 24-7-52. It will cost you electricity as filaments are not cheep, but the tubes will take it, they lasted for years. Filament life was never an issue. What is hard on filaments are turning 0n then Off a lot (the surge). Bottom line, any choice you make is okay, both methods have their own advantages. You will notice more heat in the shack.

Hello Group,
In the mid 70's I subscribed to the magazine "Ham Radio". The editor, Jim Fisk, wrote of a set he had that had been running since the end of WWII (as I recall). He made two points. (1) He never turned the filaments off, because the real damage to a set occurred from metal to glass expansion as the two materials heated/cooled. With sets that were always on the heating and cooling cycle was reduced, giving longer life. (2) He fitted a switch to turn the B+ supply off - reducing stress on HV capacitors.

In my memory the set (his set) had been running in that state for 25+ years.

Les

Hi Loren,
Welcome. I have had the same tubes on my TS530sp and TS830s since 1982...they will last a very long time as long as you tune the PA correctly and dont drive them at the limit every time. I seldom run more than 80watts.

Dear Peter,

The YG(Golf)-88C does not match for the TS-830S, only in the TS-820S.
For your TS-830S use the YK(Kilo)-88C - 500 Hz.

Please look this link:

The TS-820 and TS-830 have the same "8.83Mhz" IF frequency. Whether an 820 8.83Mhz filter will "physically" fit and install in the 830s 8.83Mhz slot, I don't know. The same goes for the 8.83Mhz 820 CW filter.

The TS-830 is a 'dual conversion' transceiver where as the TS-820 is a 'single conversion' transceiver. What does that mean? It means the TS-830 has "2" sideband filters, one at 8.83Mhz and the other at 455Khz. The same goes for CW, one for 8.83Mhz and the other for 455Khz. When changing filters in the TS-830 it is wise to change both the 8.83Mhz AND the 455Khz filters so they match in bandwidth.

Personally, even if the 820 filters fit in the 830, I wouldn't do that. If you have a TS-830 and it is lacking a CW filter, my advice is to purchase the 2 CW filters, 8.83Mhz and 455Khz, for the 830 and not mess around with mixing different filter bandwidths etc.

Thanks for all the feedback. I'm new to tubes and appreciate the help. I'm a computer guy by trade, and have machines that have been running years and only are cycled for updates. I've always preferred to leave electronics on.

Thanks for the help!

One additional comment.

In receive the transmit circuits that are not associated with receive, are biased to cut off (turned OFF), even the driver and both final tubes. In receive the driver and both final tubes do not conduct, only the filaments are glowing/lit, no current flowing in the tubes.

There are a few "common" circuits, circuits that work in both transmit and receive such as the VFO, carrier generator oscillator, IF stages, and power supplies. Those circuits will remain on but none of them are not controlled by the Heater switch. As I said earlier the only thing the heater switch controls is the driver and both final tubes filament voltage, nothing more.

I would not recommend leaving the radio on 24/7 365 days a year but letting it be powered on and sit idling during the day while you do other things will not harm the radio.

29550. TS-530S display flickers with bandswitch

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-29 14:23:02 UTC
From: Philip Hahn
Topic: 29550 Message: 29550

My TS-530S's digital display flickers on/off with the bandswitch rotation. At some positions the display is dead, at others it comes back on. Sometimes at a single band position, if the switch is wiggled a little, it will flicker and come back on.

Any ideas where I should begin my search?

thank you,

philip hahn, KI4VUP

29551. Ts 820s needs help

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Hello to the group
I am a new poster to this group, but have been following this site for quite some time. I have learned many things from this group, and I thank you all.

I have a ts820s that needs to be saved. I have surveyed the unit repeatedly to find changes that may have been made over the years.

The findings I can see are the digital display and 5 volt power board have been removed.

The DC to DC converter has been removed.

Everything else looks very normal. The radio powered up and only heard white noise.
I then found both relays and the contacts looked very good almost new but the base terminals were grungy. I cleaned all the terminals and sockets with deox. Also cleaned the contacts inside.

Now the radio receives only strong stations with 80 mtrs being the best and deteriating on all other bands.

S meter only reads abt 3 on signals showing 10 to 20 over 9 on my ts440s.

The marker system works although not registering on s meter.
WWV I don't hear
I did some basic voltage checks the 3.3 volt is Ok at points that it should be. 9 volt also is good.
However I have a problem with the 14 volt line it only shows 12.5 volts. The 4 diodes all look visibly to be intact, no cracks but at the output it is only 12.5 vts.

So that is the current situation and I am hoping to learn more about these great radios.
Any ideas to further investigate would be appreciated.
Thanks to all. Dale WN0WWY

Phil,

More than likely the "wafer switch" contacts/wipers are dirty...try some DE-OXIT. Make sure also that the bandswitch coupler is not partly broken/loose. This is in the final cage area and connected to the end of the bandswitch. There are 4 small allen screws to hold it in position...very common to have one or more of the set screws crack the plastic coupler. Just make sure..if you go into the final area to make sure ALL THE VOLTAGE IS GONE..there's a lot of HV in there. Rotate the bandswitch back and forth and watch the coupler. It is usually obvious if there is/are cracks around the screws..use lots of light..you might also see the cracks... good luck

Dale:

12.5 VDC on the 14 VDC line is not a problem. My TS-820 is that way and I even blew out some of the rectifier diodes in the process of trying to figure out why the voltage was "low." Replacing the diodes just brought it back up to 12.5 V.

The most likely problem with the receive section is a poor alignment. You should align the carrier frequencies (especially of the received SSB signals sound unintelligable or even just not quite right) and then peak the coil pack for each band. There are three sections of the coil pack for each band.

It is better to use a signal generator as an input to peak the coil pack but it can be done using the built in calibrator. You must exercise great care in tuning the coil cores. For adjusting the smallest cores do the following:

Take a 3/16 in wooden dowel and file the end down so it is pointed like a chisel, flat on two sides. Then cut each side of the chisel point off so it is only just wide enough to fit the smallest coil forms. Then cut the very tip down so it is a bit blunt.

You can file the other end of the dowel down to a chisel point too and then cut the very tip off. It will be useful for the larger coil cores.

Then, preferably, dip the whole thing in a varnish and let it dry.

A slightly larger diameter dowel can be filed down to a blunt chisel shape as well in a similar mannner and will be useful for tuning the neutralization screw in the final amp. You can get a whole bag of assorted dowels at Wal Mart for about $1.50.

Follow the procedure in the TS-820 manual for peaking the coils. It is basically very simple. Exercise care since there are high voltages exposed on the RF Driver board that sits 90 deg to and above the coil pack.

Good Luck!

Robert

Greetings group,

Can anyone tell me what is the function of the transformer located on the underside of the 520 back by the "carrier board" It is stenciled "L15-0002-15." This is the same rig that had a CB hack..which was removed...and now has no audio..except on WWV/JJY. I had it turned on and after about 2-3 minutes, noticed a "burning smell." Turned off rig, removed covers, and located the source....it was so hot...it took about 10 minutes before it could be touched. What does this item do? Oh, Mike(w5rkl) this is the one I was working on before.

Joe,

The current flow through the CH choke is quite low except during transmit when the 2 relays are energized. Even then the current level is low.

If the CH Choke runs "hot" then it's possible one or more of the following is at fault

1. Short in CH Choke windings
2. Faulty filter capacitor C33 (high internal leakage current)
3. One or more circuits pulling too much current from the 14VDC supply

The CH choke should not run "hot"!

Hey Joe, it sounds like yours is doing what mine is getting ready to do. Mine isn't at the point of burning up yet, but it is dropping almost 3 volts so my "14V" supply is actually reading about 10.8. Coils can become more resistive as they age and the higher internal resistance they have the more of a voltage drop they will have.

You'll probably have your 14V on your Rectifier unit and your Vox unit, but I'll bet your input voltages to your AF Unit, Carrier Unit, NB Unit, FIX CH AVR Unit, RF Unit and your IF Unit all have lower input voltages because the voltage being dropped across your Choke. This could also be why you're not getting any audio output.

I found this on my 520 recently and ordered a replacement Choke to hopefully correct it. Even with the 3 volt drop across it, my Choke doesn't get hot and yours shouldn't either.

Also, there are 2 electrylytic capacitors C33 and C34 wired to either side of that choke and I suppose if C33 were to short then you would have a direct short to ground and no 14V to the boards mentioned above and you would see about a 14V drop across the Choke which I am sure would make it really hot! So you might want to replace both C33 and C34 or at least check them out. I replaced mine which is how I ended up blaming the Choke itself for the voltage drop.

Hope this helps.

Mike & Steve,

TNX for the insight! As I have stated before...I'm NOT the sharpest pencil in the "diagnostic box." This is rather a clean rig...and I want to get it back to its original "glory." I like old things...that's why I also live in a 110 year old house....old things may take lotsa TLC...but they are worth it...ask the XYL...oh dang...she saw that...we're only 6 months apart...but trying to explain XYL to non a ham...gets lost in the translation..but ya gotta love 'em. Let you know what I find.....Oh... Steve...from whom did you order your choke...and what part #.....

Thanks Robert for the input I will pursue the alignment procedure. I was sure curious about the 14 vt line Thanks again.

Subject: [TS-520_820_530_830] Re: Ts 820s needs help

Dale:

12.5 VDC on the 14 VDC line is not a problem. My TS-820 is that way and I even blew out some of the rectifier diodes in the process of trying to figure out why the voltage was "low." Replacing the diodes just brought it back up to 12.5 V.

The most likely problem with the receive section is a poor alignment. You should align the carrier frequencies (especially of the received SSB signals sound unintelligable or even just not quite right) and then peak the coil pack for each band. There are three sections of the coil pack for each band.

It is better to use a signal generator as an input to peak the coil pack but it can be done using the built in calibrator. You must exercise great care in tuning the coil cores. For adjusting the smallest cores do the following:

Take a 3/16 in wooden dowel and file the end down so it is pointed like a chisel, flat on two sides. Then cut each side of the chisel point off so it is only just wide enough to fit the smallest coil forms. Then cut the very tip down so it is a bit blunt.

You can file the other end of the dowel down to a chisel point too and then cut the very tip off. It will be useful for the larger coil cores.

Then, preferably, dip the whole thing in a varnish and let it dry.

A slightly larger diameter dowel can be filed down to a blunt chisel shape as well in a similar mannner and will be useful for tuning the neutralization screw in the final amp. You can get a whole bag of assorted dowels at Wal Mart for about $1.50.

Follow the procedure in the TS-820 manual for peaking the coils. It is basically very simple. Exercise care since there are high voltages exposed on the RF Driver board that sits 90 deg to and above the coil pack.

Good Luck!

Robert

Hey Joe,

I ordered the Choke from Bob Mansker KE5FTF. His e-mail is ke5ftf@....
It's a used but fully functional part and only cost me 8 bucks before a very reasonable shipping charge. I believe Mike was the one who suggested him to me a while back and after contacting him I can see why. He says he has about 50 of these rigs and he's parting them out. If you are looking to replace C33 and C34, (2200uf 25V electrolytics) I got mine from Mouser Electronics who always seems to have the discrete components that I need. Shipping to me here on the Right Coast Priority Mail takes about 3 days.

And don't worry about not being too familiar with the 520's innards. It comes with time. I'm still learning all the time thanks to Mike W5RKL. I've been working on mine off and on for the last month or so and can't wait to get it back on the air as well!

And Mike, in case you see this, I ordered a spare Antenna Coil Unit from Bob as well so if my problem does end up being my ACU then I'll just replace it instead of re-wrapping L1 all over again! hehe

29562. Re: function of part in TS-520

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-01-30 04:55:25 UTC
From: w5rkl
Topic: 29554 Message: 29562

The 14VDC filter is a capacitive input filter with a choke.

A failure in C34, the capacitor before the choke, will not cause the choke to overheat. C33, however, if it shorts internally or has high internal leakage current, will cause higher current to flow through the choke which can result in the choke running warmer/hotter.

Before you replace the CH choke, determine what is causing the choke to overheat. I do not recommend operating the 520 until you determine what is causing the CH choke to overheat. Further overheating can permanently damage the choke. While overheating a choke can result in shorted windings, a short duration of overheating may not always destroy the choke. When a transformer, choke, or other coils overheat due to excessive current flowing through the coils/windings, the long term heat melts the insulating enamel coating on the winding wire. When this occurs the windings short to the transformer or choke metal core. In RF transformers, the insulating enamel coating causes the windings to short resulting in a short to ground to RF, if the coil is grounded at one end. If the coil is not grounded, the inductance of the coil significantly changes resulting, quite often, in the coil no longer resonating on the desired frequency.

I agree to replacing C33 and C34, both 2200ufd 25VDC electrolytic capacitors. The important capacitor is C33 the output filter capacitor. Since you do not know the physical and electrical state of either capacitor, it makes good sense to replace both.

It's important to understand that simply replacing both capacitors should not be considered the fix to the overheating of the CH choke. Troubleshooting the 14VDC supply and circuits connected to it will determine what is causing the CH choke to overheat.

Not wanting to prolong this thread when all wise advice has been given, but my understanding has always been that the switch to turn the heaters off was provided to save battery power when working with the optional 12V converter.

I was cleaning up my 520 and wish I hadn't looked inside. While the rig works pretty well it looks like heck inside. I found 4 resistors near the transformer that look burned. I have put pictures in a folder called KD0ILM in the pictures of this forum. I wonder if one of you fine fellows can tell me what they are.

The photos, you have provided, in the folder appear to be the High Voltage Board. R5 and R6 on the HV board, the two that appear burnt, are the resistors that drop the voltage down for use in the "TUNE" mode. Are you having problems with the TUNE mode not working. Are you able to use the TUNE mode during tune up?

Kevin,

Did you remove the mounting screws holding the HV Unit board to the chassis or is this how you found it?

Not all resistor that looks like the one in your picture are bad. Some discoloration occurs due to the environment. There does not appear to be any physical damage, cracking, blistering, or out right burnt/overheated bodies of these resistors. The only way you can determine if these resistors are bad is to measure them with an ohm meter. Don't guess whether they are good or bad, check them to be sure.

If you do not have the manuals then I recommend downloading them from Gordons' website

www.n6wk.com/kenwood/

You can also determine whether the resistors are bad or not is by measuring the voltage at the destination point, final tube screens. If the resistors are bad then the voltage at the destination will be less.

Carbon resistors tend to "increase" in value (resistance) by just sitting around.

Carbon resistors tend to "decrease" in value (resistance) when they overheat due to circuit failure.

Do not assume these resistors are bad. Always check the component first and never replace a component simply because it's old. That's very poor troubleshooting techniques, not to mention wasteful and can easily lead to additional problems the radio didn't have.

73s
Mike
W5RKL

Hi Everyone,

Aligned my TS-830s last night using Sig Gen, Frequency Counter, RF Voltmeter etc. All aligned really well and on-spec.

The only issue I have is that on transmit, (monitoring on my FT-990), on USB I am slightly low on frequency and on LSB I am slightly high on transmit frequency.

Any ideas?

Thanks, Chris ZL1CDP

Yes sir Chris,

It sounds like your carrier frequencies are off slightly but then again perhaps you already set them to spec....

Hi Chris,

I can't really say, I had three 830's but sold them all. I do remember an adjustment for CW,USB and LSB carriers to center them in the filter passband. It made a significant Difference as all three units I bought needed tweaking for USB/LSB. If you switch between USB/LSB on a clear frequency the pitch of the noise should be roughly the same for both USB and LSB. I believe the manual states what the frequencies for each should be, I used a frequency counter to monitor the adjustment.

No sir, I am not aware of any other adjustments but hopefully someone with more current knowledge of the 830 will respond.

If the frequencies are correct it is possible that the crystal filter in your radio has aged and shifted its band pass. I have seen this on a couple of older radios.
In that case I set one so that receive sounded balanced audio frequency wise, then I tweaked the other sideband crystal so that background noise sounded similar.

Greg

Chris,
Be sure to check that the LSB Rec and TX frequency is the same as in
step 3 of the service manual.
If not, you adjust VR2 until it is in LSB. Once that is set, then you
adjust the TC2 LSB and TC3 USB for the proper frequency.
For CW you adjust VR3 to get the correct offset. all these are on the
PLL board
Is master Osc at 10.00000 ?

73,
Gordon

From: Allan C
Topic: 29578 Message: 29578

With sadness I post this report of one of our own here in Norman, Oklahoma.

We received word that Duane Olinger, KD5IOS, passed away from viral pneumonia on the evening of January 13th. Our condolences go out to his life partner, DeAnn, and son, Scott. Duane was an active ham, and though a retired aerospace engineer, he kept himself busy working in the community in many different pursuits. SCARS and the entire community will miss him.

I hate to break this to you Kevin, but according to the pictures, this is not a 520! LOL It's a 530, much different animal. I know I'm being a pain of a stickler, but we all seem to lump the 520 -830 series in a group and many of us, (myself included) sometimes call them all 520 series radios. I know in my case that it's just old age creeping upon me. If you hadn't posted the pics, I'm sure many of us would be mentally trying to troubleshoot a 520, while we should have been thinking about a 530! As we used to say back in Maine : "It's the same, but different!"
Carry on the good quest! It deserves to be brought back to it's original glory! Good luck, and listen to the good advice from the group!
Jeb Brygider KE7LIU (only been doing this since 1959, and learning new stuff every day!)

Hi Gordon, thanks for the response.

Yes, as per the service manual, LSB TX/RX is the same frequency and the CW offset is correct too.
Master Osc at 10.0000? - Not sure... Where do I check for that?

Cheers
Chris

Hi Chris,
Connect your freq counter to TP2 on the PLL board. It should be 10.0000,
if not adjustTC1 on the PLL board until it is.
If your LSB TX and Rx are the same, then your receive and TX freq should
also be the same unless you have a problem on the RIT circuit.
Make sure the RIT stays the same when at zero, whether button in or out.
If not, then adjust VR2 on the AF board until it is.

73,
Gordon

Hi Gordon, appreciate your help.

I will check the 10Mhz Master oscillator readout in about an hour when I
get home from work.
The RIT checks out the same when in and out (frequency wise).

Thanks again, I would love to get her working well!!

Chris

Topic: 29570 Message: 29584

Hi Chris,
That is very strange that the TX and RX frequencies don't match then.
Have you checked the output with a freq counter and a loop around the
coax? Does it match the Digital display on the 830?
Never TX into the counter directly however :-)
Maybe The only thing you could do is tweak the caps on the PLL board for
USB and LSB to get them to be on, or maybe the 990 is off?
How far off does your 990 show the 830 is?
I have never had this issue in any of the 830's I have aligned.

73,
Gordon

From: Chris Parnell
Topic: 29570 Message: 29585

Gordon I will mail you directly, take it off the reflector bandwidth if thats ok with you.

Thanks
Chris

29586. Re: TS-830s alignment question.

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-01 08:07:08 UTC
From: paulrshinn
Topic: 29570 Message: 29586

My 830 TX and RX are off by a BUNCH. The displayed TX freq. is correct, but when it switches back into RX mode, the freq. display reads 7 kc. off. Actual RX freq. is OK, just the display is way off. How would I fix that? If I use RIT, then the display might read right, but then actual RX freq. is way off.

29587. Adding a data port to an 830S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-01 17:27:45 UTC
From: Dennis Wade
Topic: 29587 Message: 29587

Good Morning everyone,

I had an idea for putting an actual rear panel connector
(actually rewiring the existing "REMOTE" DIN jack) to allow rear panel
connections for sound card/computer modes that require audio out, mic
and PTT lines.

Some time ago there was a thread that ended up with a
source for fixed level audio that would be appropriate for putting
into a sound card. In looking at this and wondering how to bring it
out of the radio with some elegance, I looked into just what the rear
DIN jacks were used for. I discovered that the REMOTE jack already
had speaker audio and PTT, plus one unused pin (pin 7).

My thought is to replace the speaker audio line with the
fixed level audio, bring a high level mic input to the now unused pin
7, and utilize the PTT line for keying.

Am I overlooking something? If someone could also look at
the schematic and give me some opinion about the value of (or not)
doing this, that would be appreciated.

Thanks!

Dennis

A quick way to tell if the PLL is the source of the frequency problem simply measure the VCO frequency at the RF Unit's VCO terminal. The VCO frequency should be the same whether in TX or RX. You will have to compare the RF Units' VCO frequency to the VCO frequencies in the 830 service manual.

>
> My 830 TX and RX are off by a BUNCH. The displayed TX freq. is correct, but when it switches back into RX mode, the freq. display reads 7 kc. off. Actual RX freq. is OK, just the display is way off. How would I fix that? If I use RIT, then the display might read right, but then actual RX freq. is way off.

Dennis,

Fixed audio is present at the AF Units' plug 2 pin 3 (AV1). However, the level of audio here may not be sufficient to drive the sound cards interface to the sound card microphone or line input connections. A scope connected here could give you an idea of the audio level.

Transmit audio from the sound card interface to the 830 can be applied to the IF Unit plug 7 pin 5. This is after the microphone preamp. Connecting at this point will allow the MIC gain to remain at it's normal SSB voice setting. The sound card interface transmit audio level pot is adjusted and not the MIC gain.

I'm not sure if I would rewire the Remote DIN socket or any of the rear panel DIN sockets for that matter. A better solution is to install 3 female RCA sockets on the rear panel, one for receiver audio, one for transmit audio, and one for PTT. If you do it right, take your time, the finish product will look professional. Use shielded cable, simple interconnecting cables used to connect VCRs to stereo amplifiers will work fine. Run the shielded cables along the wiring harness and tie wrap them to the wiring harness after the connections have been made. Black cables are good for this.

Just my 2 cents.

Thanks Mike. Those are good ideas. The pin 3 audio will need to be checked before I use it, but it was the answer given in the earlier thread.

Has anyone else used the audio from plug 2, pin 3 (AV1)?

The RCA jack idea is a good one, but the point was to not have to do any drilling, etc to accomplish the task.

That is still an option though.

Thanks!

Dennis

I don't know if anyone else has used the AV1 audio or not. AV1 is fixed audio level from the audio preamplifier which is most likely in the "mv" (millivolt) level.

I understand not wanting to drill holes in the rear panel. The rear panel would have to be removed and the holes lined up horizontally so they are even and a punch used to make a mark so the drill bit doesn't wander around. Just a thought.

Hi All,

Just a quick update to let you know that I found the culprit to my misaligned TS-830s and all is now correct and on frequency.
Thank you to all that replied, and a special thanks to Gordon N6WK for his guidance.

Now☐ On to replacing the cathode resistors under the finals to bring the current down to 225mA.

Cheers
Chris, ZL1CDP

A quick way to tell if the PLL is the source of the frequency problem simply measure the VCO frequency at the RF Unit's VCO terminal. The VCO frequency should be the same whether in TX or RX. You will have to compare the RF Units' VCO frequency to the VCO frequencies in the 830 service manual.

>
> My 830 TX and RX are off by a BUNCH. The displayed TX freq. is correct, but when it switches back into RX mode, the freq. display reads 7 kc. off. Actual RX freq. is OK, just the display is way off. How would I fix that? If I use RIT, then the display might read right, but then actual RX freq. is way off.

29593. TS-520S Crystal Calibrator question

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-01 23:48:13 UTC
From: John
Topic: 29593 Message: 29593

I am having difficulty when using the crystal calibrator on my TS-520S. It gives me birdies about every 25kHz as expected, but they do not occur at even 25kHz VFO markings. I have calibrated my DG-5 to WWV (15.000 mHz) and several stations come in as expected by the DG-5 indications, but the calibrator is off about 1.5 kHz or so.

I have tried to zero beat the calibrator against WWV as per the manual, but it won't line up. Maybe I'm doing something wrong, but a "zero beat" to me means the tone decreases in pitch until it goes away (the "zero beat" and then rises again in pitch. The calibrator tone goes from low pitch to high pitch to low pitch across the range of about 2 khz, which seems the opposite of zero beat. I have also tried using a frequency counter, per the service manual (counter at test point MO on Marker Board). I am unable to get a stable frequency reading to set the calibrator. What am I doing wrong?

John KD5ZGX

Good luck...JD
I have tried to zero beat the calibrator against WWV as per the manual, but it won't line up. Maybe I'm doing something wrong, but a "zero beat" to me means the tone decreases in pitch until it goes away (the "zero beat" and then rises again in pitch. The calibrator tone goes from low pitch to high pitch to low pitch across the range of about 2 khz, which seems the opposite of zero beat. I have also tried using a frequency counter, per the service manual (counter at test point MO on Marker Board). I am unable to get a stable frequency reading to set the calibrator. What am I doing wrong?

John KD5ZGX

  Using WWV can be tricky due to the 400 and 600 hZ tone modulation in most of the minute cycle. You should do your Zero beating while the second ticks are sent without the tone.

Just ordered and rec'd 5 NOS GE 6146Ws from Tube Depot. They were ON SALE, 5 for 14 bucks each, just add 4.95 for FEDEX ground shipping...best deal I have found and I have been all over the internet looking for past 2 weeks....packed really well as well...if you need some, check it out for yourself. Randy, KA4AQM

29596. TS-820S loses receive when I plug in a D-104 mic

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-02 02:46:37 UTC
From: jwimmer@bellsouth.net
Topic: 29596 Message: 29596

I have a TS-820S and while it receives great, if I plug in any of the 3 D-104 mic's I have, I kill the receive audio. I have checked to make sure the mics are wired correctly as follows:

Pin 1 - white
Pin 2 - red
Pin 3 - black
Pin 4 - shield

Pin 1 and 4 are mic, 2 and 3 are key. Everything to me looks fine, but I can't for the life of me figure out why this might be happening!

Any words of wisdom from veteran 820 owners who like the Astatic mics would be humbly and greatly appreciated!

Thanks much
Jeff

Thanks Scott. 2 of them are the T-UG8 base, and they do have the E/R switch. I had read in some other forums, on QRZ and maybe it was Hamuniverse I saw it on that these old D104's should be in relay mode. I have switched the 2 T-UG8 mic's to the relay position, still no joy. The third mic is a T-UP9 base and I won't even bother with it until I get the 2 other mic's working. I keep wondering if it's shorting out the mic input.

29601. Re: TS-820S loses receive when I plug in a D-104 mic

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-02 05:51:46 UTC
From: w5rkl
Topic: 29596 Message: 29601

Does the 820 switch from receive to transmit, meaning the relays energize when the microphone is plugged into the 820 without the PTT bar squeezed? If this is what is happening then the microphone wiring inside the base and the 4 pin microphone plug is wired incorrectly.

The microphone itself, when properly wired, has nothing to do with the receive audio unless, as I said above, the 820 switches from receive to transmit due to bad wiring. I also would not rule out shorted microphone connections at the plug or in the microphone cable itself.

Looking at the 820s' front panel microphone socket, the top 2 pins, 3 and 2, are the PTT pins. If these pins are shorted together the 820 will switch from receive to transmit, disabling the receiver which leads to loss of receive audio.

Remove the microphone element from the top of the D-104 stand by loosening the nut at the base of the top microphone element. Once the nut is loosened completely pull the top off of the stand. This is important to ensure the element is not subjected to DC voltage from an ohm meter.

The PTT bar must not be squeezed by your hand or the PTT slide bar, if so equipped. Some D-104 microphones have had the slide bar removed.

Looking at the 4 pin microphone plug, with the curved portion at the bottom, the top 2 pins are pins 3 and 2, PTT. Connect an ohm meter between these pins without squeezing the PTT bar. If the ohm meter shows a short then the microphone wiring is wrong.

A properly wired D-104, with the ohm meter connected between pins 3 and 2 on the microphone plug, squeezing the PTT bar should cause the ohm meter to indicate a short. Releasing the PTT bar should indicate an "open".

Hi all,

Just replaced the cathode resistors (that were blown) in my final unit underneath the PA on the TS-830s.
After reconnecting the final unit board with screws and putting tubes in and plate caps on top, I then obviously fitted the PA shield casing.

Turned on and there is no frequency display!!!!! Grrrrrrrrr☐. Any ideas what could have gone wrong?

Thanks
Chris, ZL1CDP

I have a 520S and a 530S. Will a D-104 with the amplified T-UG8 stand match up with these radios as far as impedance goes? I read where the amp was an attempt to match the old crystal element to the newer radios. Also, would it be a good idea to replace the electrolytic caps on the amplifier of this mic?

The amplified D-104 has a low impedance which will work okay with the 530 but not the 520.

Why or what makes you believe the electrolytic capacitors need replacing? Is there a problem with the microphone amplifier that, through troubleshooting, the source of the problem points to one or more of the electrolytic capacitors as the source of the problem or are you thinking of replacing the capacitors simply because they are old?

I mean no disrespect but if you are thinking of replacing the electrolytic capacitors simply because you were told or you read where a ham or group of hams believe it's good insurance to replace them because they are "old" then that's wasteful, poor troubleshooting/maintenance practice, and just pure non-sense!

Replacing any component, regardless of what the component is, should ONLY be done "if" there is evidence through troubleshooting that proves that component(s) has failed! Don't fall for this "it's good insurance.." or "they're old so they will fail soon.." non-sense. Therefore, unless you have solid evidence that one or more electrolytic capacitors, or any other components for that matter, is/are a source of a problem with the microphone or any other electronic equipment, do NOT replace them!

It'll be good to have fixed audio levels for receive and transmit like other radios without mentioning any brand names.

I am wondering how the rest of us did our wiring.
I took the receiver output via a resistor at the rear speaker jack and on transmit use the mic socket and ensure the processor is switched off.
Thanks guys I'll have a look at the AV1 fixed audio level to see if there's enough level.
I don't think I would like to cut any more holes or modify the factory wiring as it's for something else.

For sound card modes bypassing the processor is more important for me.

As techs are never satisfied.

Topic: 29587 Message: 29607

Aisea,

I have used the MIC socket for PSK, RTTY, and SSTV sound card transmit audio and receiver audio to the sound card by parallel connections to the speaker. I don't care for this arrangement.

The TS-520S, TS-520SE, TS-820, and TS-820S, have Phone Patch IN and Phone Patch OUT sockets on the rear panels. Unfortunately, none of these sockets provide for fixed audio levels, whether it's receive audio or transmit audio. The Phone Patch IN audio level from the sound card interface to the transmitters' speech amplifier is controlled by the MIC gain. The Phone Patch IN audio level from the radio to the sound card is controlled by the volume control. Again, no fixed audio at any of these transceivers' phone patch IN/OUT sockets.

Mike et al,
You are very correct about poor troubleshooting form. I have burned myself countless times by replacing or fixing things that do not need fixing. Other than slightly lower output than the book might say (and who is to say if my wattmeters are accurate) and an S meter that doesn't zero out the radio works fine, plenty of drive etc.

I guess I was really horrified when I opened it up. I have two other Hybrids and they are fairly clean looking inside. This one looks horrible even though it works well. Maybe it belonged to a smoker and that contributes to its internal bad looks. The face place is quite worn by the load knob and send switch so I guess it was also used a lot. At any rate I am going to take a step back and proceed with more caution and good form.

Do you know if I can test those resistors in place?"
Kevin KD0ILM

From: Chris Parnell
Topic: 29610 Message: 29610

Hi all,

Has anyone used the Philips QE05/40 tubes in Kenwood Hybrids? They are the equivalent of the 6146B I believe□. I have two new ones that came with the 830 and wondered if they were reliable.

Thanks
Chris, ZL1CDP

Kevin,

Yes you can test/measure the resistors in place but the resistance will be less than each individual resistor. This is normal since the resistors, R2 and R3 (both 10 ohms each) are wired in "parallel". The resistance should be around 5 ohms (2 x 10 ohms in parallel -- 10 x 10 / 10 + 10 = 5). When measuring R2 and R3, set the 520s' meter switch to a position other than IP. You can also measure resistors R6 (100 ohms) and R4 (3.3K) also with the meter switch to a position other than IP.

29613. TS-520S VFO Knob Issue

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-03 14:19:33 UTC
From: John
Topic: 29613 Message: 29613

Over the weekend, I took the VFO out of my TS-520S to clean and relube the gear train because it was gritty in operation. I'm an engineer, so this should be no problem, right? After all, it is just a simple mechanical mechanism. No problem removing it, cleaned and relubed the gears ok. Opps... I tugged a little too hard on the shaft the knob goes on and suddenly I had it in my hand. I tried to put it back in, but it clearly wouldn't go. Took the black knurled fitting off, and four little balls fell out - 2 bigger ones, two smaller ones. The outer hollow shaft attached to the pinion gear has three holes, and there is a groove in the inner shaft, so I postulated that one ball goes into the hollow shaft as a base bearing, and the other three go into the holes to retain and act as a planetary gear set, retained by the bearing race inside the black knurled fitting.

So much for logic - which ball goes where? No matter how I assemble the mechanism, it either has too much slack and the knob spind without reliably turning the VFO, or it is very hard to turn, yet very positive. Right now, I would more than settle for the previous gritty feeling. Help!

John KD5ZGX

29614. Re: Philips QE05-40 tubes in Hybrid as finals

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-03 16:29:48 UTC
From: w5rkl
Topic: 29610 Message: 29614

Chris,

Phillips enter-electrode capacitance specifications indicate the QE05-40 is equal to a 6146/6146A, not a 6146B. This doesn't mean this tube should never be used in any of the hybrids. It simple means the QE05-40 enter-electrode capacitance values are the same as a 6146 or 6146A and not a 6146B.

Contrary to popular belief, the enter-electrode capacitance values between the 6146/6146A and 6146B are not significantly different. The difference is the Cathode to Plate capacitance which is .22pf in the 6146B and .24pf in the 6146/6146A. That is only ".024pf" difference in Cathode to Plate enter-electrode capacitance values between the 6146/6146A and 6146B tubes. It is true the 6146B has a much heftier plate which results in a lower maixmum RF power rating in the 6146/6146A as compared to the 6146B. However, .024pf does not appear to be a significant difference in Cathode to Plate enter-electrode capacitance to suggest not using either a pair of 6146A or 6146B tubes in the hybrids. One would have to keep in mind the lower power rating of the 6146/6146A if those are used. Naturally one would not "mix" a 6146A and a 6146B in the final amplifier, keep the tubes the same, either 2 x 6146A or 2 x 6146B. The final amplifiers' neutralization should always be checked and if necessary, adjusted to achieve proper final amplifier neutralization as outlined in the service manuals.

The difference of ".024pf" should be ".02pf". The enter-electrode capacitance difference between the 6146/6146A and 6146b is ".02pf" not ".024pf". Sorry about that, I was typing too fast.

John,

I had the same problem with a TS-180s, wich has more or less the same reduction gear. There should be 2 and 3 balls. The two balls go in the hollow shaft, with the spring first. For placing the 3 other balls you unscrew the copper colored bushing. You will see tree holes were the balls will fit. Push in the small axis, put the 3 ball bearings in and screw the copper bushing in it's place. For easy reassembling use some grease to fix the balls to the holes.
The only thing I don't remember is wich balls go where but that is easely found out. There should be 5 in total.

At the time (couple of years ago) I have even found a exploded view of the assembly in one of the Kenwood service manuals, but I have to search for that again in my archive.

Still hope this helps you on your way,

73, Wim PA0PGA

You certainly do not need a motorized wrapping gun for the small amount of wrapping and unwrapping that you might need to do on your radio.

Keep in mind that wirewrapping is a one time deal. That is to say, once you unwrap a wire from the terminal, you should solder that terminal to get good electrical bonding. A proper wirewrap is "gas tight" meaning that there is no chance of oxidation taking place between the wrap and the terminal. Once you unwrap and try to re-wrap that wire, this will no longer be the case.

I once had one of those little hand tools, myself. I believe I did get it from OK inc. but it has been a LONG time ago.

Good luck, Jim AG3Y

I also have had this problem...I'm not an engineer...so I know how to do it...hihi...If I remember right...take a look at the "plate" control...they are (don't quote me on this) identical...as far as where stuff goes. I have not found and internal "exploded" diagram for the VFO gear reduction. But I do remember that.....the grease/lube is real old...and "stuff" is stuck in places where you can't see it...the 3 balls of same size should be on the outside...and one smaller is on the inside hollow shaft...these things are inanimate objects...and don't care how smart you are..or what "degree" you have.....good luck.....

Subject: [TS-520_820_530_830] Re: TS-520S VFO Knob Issue

John,

I had the same problem with a TS-180s, wich has more or less the same reduction gear.
There should be 2 and 3 balls. The two balls go in the hollow shaft, with the spring first. For placing the 3 other balls you unscrew the copper colored bushing. You will see tree holes were the balls will fit. Push in the small axis, put the 3 ball bearings in and screw the copper bushing in it's place. For easy reassembling use some grease to fix the balls to the holes.
The only thing I don't remember is wich balls go where but that is easely found out. There should be 5 in total.

At the time (couple of years ago) I have even found a exploded view of the assembly in one of the Kenwood service manuals, but I have to search for that again in my archive.

Still hope this helps you on your way,

73, Wim PA0PGA

I recently returned to ham radio and I am in the market to purchase a clean, operable, ready to go on the air, Kenwood TS 520/530/820/830 series HF radio. Preferably, a TS-530. But any clean radio in the series indicated, will be appreciated. The radio needs to be shipped to Kennewick, WA, and I have a PayPal account.

Thank you...

Jeff:

Is your mike the one with 5 wires plus a shield?
If it is,
White is live audio and surrounded by the shield. Plug pin 1
Shield is audio ground. Plug pin 4
Blue is PTT common. Plug pin 3
Red is PTT. Plug pin 2
Black connects to blue when mike is not keyed and is not used with the TS-820.
Yellow connects to the shield when the mike is not keyed and is not used with the TS-820.

Unless your TS-820 has been modified, there is nothing on the mike connection on the radio that will effect the receive, so I am assuming that the receive is dead because the radio is still keyed when you unkey the mike.

Be sure that you are using the TUG-8 and not 9 base.

How many wires does your mike cord have? If it has a blue wire try connecting the Blue wire to pin 3 instead of the Black wire. Use the E position on the switch if your mike has one.

Pin 1 White
Pin 4 Shield
Pin 3 Blue
Pin 2 Red.

Let us know if this works. Let us know if this does not seem to match your version of the TUG-8.

Topic: 29626 Message: 29626

Hello everyone. My name is Mark, and I am the owner of my father's TS-830S station. I have the transceiver, SP-230 speaker, VFO-240, and AT-230. My question is this, when tuning the radio and you switch the meter switch to ALC and adjust the Drive control, all bands but 40 and 10 meters will peak with the carrier control set about 3 to 4. However, 40 and 10 require substantially more carrier. I tuned the radio on 40 meters today for the C.S.T.N. and had to crank the carrier up to bout 8. I have checked the plastic coupler on the band swith and it does not seem to have a crack in it. I am here to pick ya'll's collective brains. Have been pining for this radio for years and now that I got her, I want to get the ole girl back up to 100%. Tnx in advance for any advice you can offer.

The TS-820 receive audio is not routed through the microphone socket.

Mark,

Since the 830 was your fathers do you know if anyone, including your father, has mess with and/or adjusted the driver coils inside the 830? If the 40 and 10 meter driver coils have been improperly adjusted then that could lead to the symptoms you are experiencing.

I seriously doubt the tubes are the source of your problem nor are resistors R15 and R16 (both 56K) on the Rectifier Unit either. You might considering checking the driver coil alignment for 40 and 10 meters as outlined in the 830 service manual. When checking the driver coil alignment make sure you follow the steps exactly as indicated in the 830 service manual.

29631. 12BY7A Tube Shield

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-04 23:08:22 UTC
From: kd8hmo
Topic: 29631 Message: 29631

Is it a requirement for my 520S and 530S to have a tube shield on the 12BY7A tube? My 520S has a strange shield that resembles a ribbed condom, and my basket-case 530S had none at all. I picked up a shield for it that twist-locks on to the socket with the spring inside. Are these just for heat dissipation only? Or do they function as rf shields too?

The shield prevents RF from radiating from the driver tube to the surrounding circuits. There normally is a thin flexible rod that, when the shield is in place, rests between the shield and the driver tube. The thin rod grounds the shield.

The ribbed shield you have and other like it without the ribs are the only shields that will work over the driver tube. The twist lock shields with internal springs will not work, the hybrid driver tube socket is not equipment or designed to accept the twist lock shields.

I haven't used a shield over the driver tube in my 820 in 8 years. I have not had any RFI problems or reports of distorted audio on sideband or CW signals. The transceiver will work with or without the shield.

Yes, they are for added heat dissipation. In some configurations, the tube may not get adequate cooling and the black or gray ribbed cover is used. If it has the locking extension on the socket, it is a shield also. I have seen them both ways.

Charles,
If you can't find one, I have a good used octal plug with cover here.
$5.00 plus shipping
If you want me to wire it up and add nice Gold plated RCA plugs on the
ends, add $12.00

I have found that the shield has a significant effect on the tuning of the drive coils in the 530 and 830.

In fact, the peak drive current was higher on 15-10 mtrs.

Topic: 29638 Message: 29638

Hello all,

I am accumulating parts to build my antenna and finally get my TS-830 on the air . . . I was looking for parts to build a dummy load or a 100W dummy load to buy when I came across instructions to build a salt water dummy load that would take 100 watts. It seems that all that is required is some copper wires for the electrodes and a suitable jar as well as some salt water of the proper resistance and a connector (SO-239).

Is there anything wrong with using one of these to tune up my TS-830 initially rather than building one out of 20 resistors and some mineral oil?

I remember reading that same article about the Salt water dummy load. I'd say, sure you can use it...as long as it maintains a constant 50 ohms during operation. That's the only thing I would be concerned about. Try it and see, let the rest of us know how it works out.

Topic: 29643 Message: 29643

Hello to the group, I have just purchased another 530. I had foolishly sold my first one and missed it almost immediately,live and learn. The one I picked up has at least one problem that I have found. I have low power output into an antenna or dummy load (50-70 watts). When I am tuning the finals I have a hard time even seeing the "dip" on the plate. During the tune up, with the meter in lp the needle on the meter actually vibrates very rapidly.The needle on the meter only does this in the lp position. The only thing I have done so far is a decent cleaning and blown out the interior, I found the shield over the driver tube had the metal strap on the outside so I reinstalled it correctly. Any tips tricks or suggestions would be appreciated. Thanks Mike w2waw

Mike, just my guess, but I would suspect your High voltage capacitors in the power supply are failing. What does your high voltage read under load? I had one like this one time that got down to 5 to 10 watts out. Check those, they are easy to replace, be sure you bleed them off before you take them out.

Mike,

What initial position is the LOAD control set to? Start tune up with the LOAD control set for maximum capacitance, LOAD control knob pointing to 9 o'clock, fully CCW. Peak the ALC with the DRIVE control in TUNE mode then set the meter switch to IP and adjust the PLATE control for maximum DIP (reduction) in IP current.

The followup on the problem & solution

PA0PGA directed me to the TS-820 manual which has an exploded view of the reduction drive mechanism. I found that I was missing one of the larger balls (don't know if I lost it or it had been lost before me). Went to my local hardware store and bought 5 5/32" diameter ball bearings (0.1563" dia., approximately 4mm)., I assembled the drive with the spring and the 2 smaller balls inside the larger shaft. I inserted the axle shaft, and held it in place while I put the 3 larger balls in the recesses. I then screwed down the top bushing, Still was slightly "gritty" so I opened it up again and put lapping compound in the recesses and covering the balls. Reassembled it and spun it with a drill motor for a few minutes. Smoothed it up real nicely. I then cleaned it out and reassembled it with fresh lube. Works great now. Thanks for the help.

> > > >
> > > > Over the weekend, I took the VFO out of my TS-520S to clean and relube the gear train because it was gritty in operation. I'm an engineer, so this should be no problem, right? After all, it is just a simple mechanical mechanism. No problem removing it, cleaned and relubed the gears ok. Opps... I tugged a little too hard on the shaft the knob goes on and suddenly I had it in my hand. I tried to put it back in, but it clearly wouldn't go. Took the black knurled fitting off, and four little balls fell out - 2 bigger ones, two smaller ones. The outer hollow shaft attached to the pinion gear has three holes, and there is a groove in the inner shaft, so I postulated that one ball goes into the hollow shaft as a base bearing, and the other three go into the holes to retain and act as a planetary gear set, retained by the bearing race inside the black knurled fitting.
> > > >
> > > > So much for logic - which ball goes where? No matter how I assemble the mechanism, it either has too much slack and the knob spind without reliably turning the VFO, or it is very hard to turn, yet very positive. Right now, I would more than settle for the previous gritty feeling. Help!

TS-830's (S) sold in the U.S. were CW/SSB transceivers. TS-830's (M) sold in foreign markets were CW/AM/SSB transceivers. Maybe you have a front panel that was destined for the foreign market version. The front panel, I believe, was modified at least twice in the lifecycle of the 830. You would have to check all the issued versions of the service manual.

My TS830s, bought in the UK many years ago, has "HF Transceiver" bottom right, as has my TS530sp.

Jon,

I am the proud owner of 2 530s', 1 530sp, and 2 830s'. Only 1 830s has
the HF SSB lettering.
I looked on the internet about it, but came up with nothing. The 2 830s'
are identical except for the SSB.
Maybe someone will shed some light.
No big deal....just wondering.

I wonder if there were some early 830's, perhaps just a few, made as sort of a holdover from 820's: My 820 says SSB TRANSCEIVER (no HF), my 830 says (like one of yours) HF TRANSCEIVER, no SSB. Maybe they made a batch of 830 front panels that had both HF and SSB, and then realized that by that time SSB had become pretty standard and they did not need to include it. When the earlier rigs were made, SSB was not yet so standard so they would want to point it out.

Single sideband was used in the late 40s to early 50s and later became quite popular in the early 60s and beyond. Single sideband has been around a long time, longer than folks may think.

Topic: 29657 Message: 29657

Got my TS830s last week at long last, its sitting next to its little sister my TS530sp. Was the 830s fitted with a narrow CW filter at the factory or is that an option? Does the Wide CW filter share the same circuit as the SSB one as they both seem the same width on mine. You may gather that I haven't taken the top of the rig yet. I know the 530sp CW filter is YK 88S, will it be the same for the 830s? When using the 830 on CW I do feel the filter is rather wide compared to the 530. Or am I going to have to get a narrower one?

Subject: [TS-520_820_530_830] Salt water dummy load

Hello all,

I am accumulating parts to build my antenna and finally get my TS-830 on
the
air . . . I was looking for parts to build a dummy load or a 100W dummy
load
to buy when I came across instructions to build a salt water dummy load
that
would take 100 watts. It seems that all that is required is some copper
wires for the electrodes and a suitable jar as well as some salt water of
the proper resistance and a connector (SO-239).

Is there anything wrong with using one of these to tune up my TS-830
initially rather than building one out of 20 resistors and some mineral
oil?

Topic: 29638 Message: 29662

Walt/Roy--This may be off topic but I built a saltwater dummy load some time ago and it works great. At 100 watts RF there is not enough current to produce any electrolysis so no hydrogen gassing occurs. I used a quart wide mouth mason jar and filled it about 3/4 full of tap water. There is only very slight warming of the water after repeated loading from my TS830s. I mounted a chassis mount SO-239 connector to the lid and left one bolt hole open for venting. I used short runs of 12 gage bare copper to a couple of copper ground straps suspended in the water. It only requires a very small amount of salt. On the order of half of a quarter teaspoon. Some would say a "pinch". You have to experiment to get the lowest SWR. You have to sneak up on it and it is easy to go past it. On 40 meters my swr is around 1.1 to 1 and on 15 meters it is 1.4 to 1. You will not read 50 ohms with your multimeter. A better way to calibrate it would be with a bridge. Only problem you will encounter is that over time the weak salt solution will corrode your copper electrodes. It is a cheap and fun project. I have pictures I can send you off line if you are interested. Terry K9TW

Maybe an early 830s production thing...and then later changed to just HF TRANSCEIVER.?
The one 830s that has the SSB is serial # 1050121.

The other one is # 7070003.

I tend to agree.
I think the earlier serial numbered ones are labeled as HF SSB
Transceiver and the later ones dropped the SSB part.
Are all those out there with the SSB on it, the Silver editions ? ie,
before the 3 mil serial number or so?

29667. Pics Of My Mint TS-520S

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

Just posted a few pics of my minty 520S that I found at the local hamfest here. It is in mint condition, extremely clean inside and out. The former owner still had the original boxes, packing, manuals and hand mic with it. He also included a nice MS-50 desk mic. I was extremely lucky to find such a nice radio.

My TS520 (no-S original) says SSB Transceiver, that's ironic since I only use it on cw :D

I wonder if there were some early 830's, perhaps just a few, made as sort of a holdover from 820's: My 820 says SSB TRANSCEIVER (no HF), my 830 says (like one of yours) HF TRANSCEIVER, no SSB. Maybe they made a batch of 830 front panels that had both HF and SSB, and then realized that by that time SSB had become pretty standard and they did not need to include it. When the earlier rigs were made, SSB was not yet so standard so they would want to point it out.

Mike,

As far as I know, and my father knows, no one has been "under the hood" to make any adjustments. I have been inside to check the plastic coupler, blow years of accumulated dust and dirt from components and from inside the finals compartment(boy was that dirty!), and changed out the driver tube(seemed to increase output from radio). Beyond that, nothing has been done to it-as far as we know/he can remember. He is looking around his filing cabinet for the service manual, pretty sure he has it. Once I have my hands on it, will give it a going through.

Tnx and '73s
Mark

ince the 830 was your fathers do you know if anyone, including your father, has mess with and/or adjusted the driver coils inside the 830? If the 40 and 10 meter driver coils have been improperly adjusted then that could lead to the symptoms you are experiencing.
>
> I seriously doubt the tubes are the source of your problem nor are resistors R15 and R16 (both 56K) on the Rectifier Unit either. You might considering checking the driver coil alignment for 40 and 10 meters as outlined in the 830 service manual. When checking the driver coil alignment make sure you follow the steps exactly as indicated in the 830 service manual.

> > Hello everyone. My name is Mark, and I am the owner of my father's TS-830S station. I have the transceiver, SP-230 speaker, VFO-240, and AT-230. My question is this, when tuning the radio and you switch the meter switch to ALC and adjust the Drive control, all bands but 40 and 10 meters will peak with the carrier control set about 3 to 4. However, 40 and 10 require substantially more carrier. I tuned the radio on 40 meters today for the C.S.T.N. and had to crank the carrier up to bout 8. I have checked the plastic coupler on the band swith and it does not seem to have a crack in it. I am here to pick ya'll's collective brains. Have been pining for this radio for years and now that I got her, I want to get the ole girl back up to 100%. Tnx in advance for any advice you can offer.

29670. TS-820 with Digital display, 10 meter display fluctuating and wont stop.

Hello all, I hope there is someone out there that has had a similar problem with their 820 and found a remedy. My TS820 with digital display(not TS-820S) although with the display is essentially the same transceiver I believe, has a fluctuating display problem when I turn the band switch to any of the 10 meter settings. The 28, 28.5, 29, and 29.5 settings simply jump up and down on the digital display without stopping, and during this action the VFO has absolutely no affect on the display if I turn it CCW or CW. I have tried to very carefully adjust the TC1 screw on the IF board and by doing this I can actually make all of the bands scroll up and down, but cannot adjust the TC1 so that once the lower bands stop schooling and the VFO has control of them normally again, the 10 meter band does its random up and down scrolling without VFO control. I have located Ken's K4EAA very nicely documented band switch repair on his website, http://www.k4eaa.com/bandswitch.html , but was wondering if anyone here could offer any other suggestions that might possibly have an effect on this problem before I start this repair on the radio. I have used spray electrical cleaner on all of the contacts hoping that would do it, but it has had no affect so far. Any suggestions would be greatly appreciated. Thank you so much, Blake

Blake,

When the frequency(s) jump around, as you say...are they indicating...say at least the correct MHz range..ie: 28 = 28.xxxx etc? I just got done removing some CB hacks from 2 820S's and they did that to. I suspect that the "PLL" has become "unlocked" for those bands. Check in the service manual, Pg 52, Section 5-2. Maybe Mike(w5rkl) or Gordon(n6wk) may have other pointers...they are way more knowledgeable than me! Good luck.................

Topic: 29638 Message: 29672

Hello All,

Thanks for the comments on this. It struck me that this is RF, an alternating current, and I don't know whether it will produce much electrolysis . . . I wouldn't think so. I looked again at all the info I could find on this on the Internet. The most popular article on building one had a graph of water temperature vs load time [key down time] and he appeared to have held the key down for about 30 minutes and produce a manageable temperature rise, but no mention of any gases. The diagrams for these things show a vent hole to allow gases to escape, but I suppose one could use a rather large hole and any oxygen and hydrogen would diffuse into the air. Having been in chem lab in high school when the chlorine generator leaked and seen what that was like, I guarantee that if any appreciable chlorine were produced in the tests cited, we'd have heard about it, as the stuff is extremely noxious.

I'm going to mull this over some more . . .

73,
Roy Kersey

Topic: 29670 Message: 29673

Hello Joe and Blake,

If the PLL Unit become unlocked, for what ever reason, the digital display will be dark, nothing displayed, and both transmit and receive will fail.

TC1 on the IF Unit sets the level of the CAR Unit signal to the digital display. Adjusting TC1 will not fix the problem you are experiencing on 10 meters. Although the CAR Unit signal is used on all bands, the CAR Unit signal is not band specific, meaning there isn't a different CAR signal for each band. Adjusting TC1 on the IF Unit will not fix the problem you are experiencing on 10 meter. Adjusting TC1 will affect ALL bands simultaneously as you have found out.

The problem you are experiencing on 10 meters appears to be an improperly adjusted VCO Unit 10 meter (all 10 meter settings) VCO Oscillator in the PLL Unit. The VCO Unit adjustments are covered on page 52 of the 820 service manual under "Adjustment of VCO unit". Table 2 on page 53 lists all of the VCO oscillator frequencies and each VCO oscillator coil. The 10 meter VCO oscillator coils are T7 thru 10.

Each band has an individual VCO crystal that is selected by the band switch. The 10 meter VCO crystals are located on the PD Unit and their individual crystal frequencies are as follows:

28.0 = 33.5Mhz
28.5 = 34Mhz
29.0 = 34.5Mhz
29.5 = 35Mhz

I recommend pulling the PLL Unit and checking each 10 meter VCO crystal on the PD Unit to ensure the crystals for all 10 meter positions have the same frequencies listed above. If the 10 meter VCO crystal are "lower" in frequency then a previous owner had the 820 modified to operate on 11 meters or a frequency band other than the ham bands.

It's also quite possible all of the 10 meter VCO oscillator coils have been adjusted improperly. I also recommend performing/checking the VCO adjustment on the 820 service manual pages. The CAR signal level to the digital display is, as I mentioned before, is set by adjusting TC1.

Although the CAR Unit signal is used on all bands, the CAR Unit signal is not band specific, meaning there isn't a different CAR signal for each band. Adjusting TC1 on the IF Unit will not fix the problem you are experiencing on 10 meter. Adjusting TC1 will affect ALL bands simultaneously as you have found out.

Hello Joseph, thanks for the reply, when I turn the band switch to the 28 position, the display is slowly fluctuating between 21 and 22 MHz, mainly 22 MHz, and the kilohertz is ranging constantly between 4++.+ kHz and 7++.+ kHz, the 28.5 position is showing 21 MHz to 22 MHz and the kilohertz range from 7++.+ to 9++.+, Band position 29 is showing 21 MHz to 22 MHz with 4++.+ to 7++.+ kHz, and band 29.5 shows 21 to 22 MHz with kHz ranging up and down between 3++.+ and 9++.+kHz. And now that I went thought all that and the radio is warning up, now when I turn the band switch from 28 through 29.5 the MHz ranges from 25 MHz, to 25MHz to 24 MHz to 29 MHz. all with the fluctuating kHz digits up and down. Whew don’t really know what to say as it seems to keep changing . Thanks Blake

Blake,

When the frequency(s) jump around, as you say...are they indicating...say at least the correct MHz range..ie: 28 = 28.xxxx etc? I just got done removing some CB hacks from 2 820S's and they did that to. I suspect that the "PLL" has become "unlocked" for those bands. Check in the service manual, Pg 52, Section 5-2. Maybe Mike(w5rkl) or Gordon(n6wk) may have other pointers...they are way more knowledgeable than me! Good luck.................

Subject: [TS-520_820_530_830] TS-820 with Digital display, 10 meter display fluctuating and wont stop.

Hello all, I hope there is someone out there that has had a similar problem with their 820 and found a remedy. My TS820 with digital display(not TS-820S) although with the display is essentially the same transceiver I believe, has a fluctuating display problem when I turn the band switch to any of the 10 meter settings. The 28, 28.5, 29, and 29.5 settings simply jump up and down on the digital display without stopping, and during this action the VFO has absolutely no affect on the display if I turn it CCW or CW. I have tried to very carefully adjust the TC1 screw on the IF board and by doing this I can actually make all of the bands scroll up and down, but cannot adjust the TC1 so that once the lower bands stop schooling and the VFO has control of them normally again, the

10 meter band does its random up and down scrolling without VFO control. I have located Ken's K4EAA very nicely documented band switch repair on his website, http://www.k4eaa.com/bandswitch.html , but was wondering if anyone here could offer any other suggestions that might possibly have an effect on this problem before I start this repair on the radio. I have used spray electrical cleaner on all of the contacts hoping that would do it, but it has had no affect so far. Any suggestions would be greatly appreciated. Thank you so much, Blake

Have you removed the digital display unit and cleaned it as described in other posts in this group? Mine did the scrolling digits on the readout until I did that. The problem started on 10 meters and gradually spread to the lower frequencies. Once I gave everything a thorough cleaning with deoxit, all went away and everything is functioning normally again. Mine is a TS-820S that had been stored in the bottom of a closet for several years, so pretty much everything was in need of a good cleaning. Tom KD7CDC

Wow, thanks for such a detailed explanation Mike, you can't know just how much it is appreciated. I was truly hoping that this problem was not a major mechanical issue as much as an adjustment issue. (although I am not afraid to tackle either) I am burring my head into the service manual and will study it extensively before trying to do any adjustments. Thanks for pointing me into what appears to be the right direction. I guess I just never had any idea that someone would ever change something to receive the CB" bands, at least not on one of these beautiful pcs. of history. LOL oh well, I learn something new everyday of my life. I guess that what makes living so great. Thanks again Mike, Blake KF7HHC http://www.pnwmetalcrafters.com/Commercial.html

Subject: [TS-520_820_530_830] Re: TS-820 with Digital display, 10 meter display fluctuating and wont stop.

Hello Joe and Blake,

If the PLL Unit become unlocked, for what ever reason, the digital display will be dark, nothing displayed, and both transmit and receive will fail.

TC1 on the IF Unit sets the level of the CAR Unit signal to the digital display. Adjusting TC1 will not fix the problem you are experiencing on 10 meters. Although the CAR Unit signal is used on all bands, the CAR Unit signal is not band specific, meaning there isn't a different CAR signal for each band. Adjusting TC1 on the IF Unit will not fix the problem you are experiencing on 10 meter. Adjusting TC1 will affect ALL bands simultaneously as you have found out.

The problem you are experiencing on 10 meters appears to be an improperly adjusted VCO Unit 10 meter (all 10 meter settings) VCO Oscillator in the PLL Unit. The VCO Unit adjustments are covered on page 52 of the 820 service manual under "Adjustment of VCO unit". Table 2 on page 53 lists all of the VCO oscillator frequencies and each VCO oscillator coil. The 10 meter VCO oscillator coils are T7 thru 10.

Each band has an individual VCO crystal that is selected by the band switch. The 10 meter VCO crystals are located on the PD Unit and their individual crystal frequencies are as follows:

28.0 = 33.5Mhz
28.5 = 34Mhz
29.0 = 34.5Mhz
29.5 = 35Mhz

I recommend pulling the PLL Unit and checking each 10 meter VCO crystal on the PD Unit to ensure the crystals for all 10 meter positions have the same frequencies listed above. If the 10 meter VCO crystal are "lower" in frequency then a previous owner had the 820 modified to operate on 11 meters or a frequency band other than the ham bands.

Hey guys,

I just wanted to post an update to what I found in case it may help someone searching the threads in the future.

My receive problem was caused by a few things.

The first thing I found was that L1 on the Antenna Coil Unit was shorted as seen by RF so the received signal was not properly coupling
from the primary side of L1 to the secondary side of L1. This also caused my marker signal to not be seen on any band. I re-wrapped both the primary and secondary coils with a 26 gauge magnet wire and tuned the coil for maximum signal transfer. At this point I could finally see meter movement when I had the marker signal engaged and the received tone sounded good in my external speaker, but received stations were garbled.

The audio was still very distorted and reminded me of listening to FM signals over an AM receiver. I used a scope to look at the output of the balanced detector and the detected modulation looked very clean.

I then connected my Radio Shack amplified speaker to the output of the detector circuit and could barely hear it because of the lack of amplification at this point but I did hear the detected signal quite clear.

That led me to the AF Unit which had 2 extremely hot power transistors on it. This AF unit also appears to have been causing a 3 volt drop to the other cards on the 14V bus. So I ordered a known good card from Bob Mansker KE5FTF and swapped out the defective one. And voila, smooth clean audio came blaring out of the external speaker!

I'm going to rebuild the defective AF Unit to keep as a spare. I also ordered a spare Antenna Coil Unit from Bob and may even replace mine if I can't get the receiver to align to specs.

Now she just needs a good alignment and hopefully we'll be set!

Thanks Mike W5RKL for your help on this!

Mike,

Tnx fer the extra info. International Crystals came through with flying colors on replacement xtals for the "CB HACKS" Now have 3 repaired "PLL BOXES" just in case I run into that again. Agn..tnx!

It's also quite possible all of the 10 meter VCO oscillator coils have been adjusted improperly. I also recommend performing/checking the VCO adjustment on the 820 service manual pages. The CAR signal level to the digital display is, as I mentioned before, is set by adjusting TC1.

I'm glad your 520 is up and working. It's always good to hear from folks after they troubleshot/tracked down the source of a problem. These are very good learning tools for owners as this helps them understand how stages work, what the signal path is and how the signal is processed throughout the transceiver in both transmit and receive. Great job Steve!!

> from the primary side of L1 to the secondary side of L1. This also caused my marker signal to not be seen on any band. I re-wrapped both the primary and secondary coils with a 26 gauge magnet wire and tuned the coil for maximum signal transfer. At this point I could finally see meter movement when I had the marker signal engaged and the received tone sounded good in my external speaker, but received stations were garbled.

Blake,

All of the Kenwood hybrids, along with a number of other manufactured ham transceivers, are candidates for CB Hackers and quite a few have appeared here. Some manuals even have the modification written at the end of the manual. I have a TS-530 operators manual I downloaded from the Internet that has hand written instructions on how to modify the 530 for 11 meter operation. While it appears to some to be illegal to modify a TS-530 for 11 meter operation, it's not "illegal" to do that. It becomes "illegal" when one "transmits" on non-ham bands, excluding MARS modifications, using a modified TS-530.

I was truly hoping that this problem was not a major mechanical issue as much as an adjustment issue. (although I am not afraid to tackle either) I am burring my head into the service manual and will study it extensively before trying to do any adjustments. Thanks for pointing me into what appears to be the right direction. I guess I just never had any idea that someone would ever change something to receive the CB" bands, at least not on one of these beautiful pcs. of history. LOL oh well, I learn something new everyday of my life. I guess that what makes living so great. Thanks again Mike, Blake KF7HHC

I agree SSB has been around for a long time, but it was far from the "standard" for voice QSOs that it is on HF now. Notice it was almost nonexistent in WWII equipment, and it sure did not jump into prominence instantly among those (i.e. hams) who had less money than the military!
When I was a ham in the 50's and 60's it was something most of us read about in QST but knew we would never be able to afford or build. The old articles on SSB equipment make a point of how it is the coming thing, if you go back and look at them, but like PC networking it was the coming thing for a long time! So I could imagine a marketing guy well into the 1970s thinking they needed to point out the transceiver did SSB.

Maybe they made a batch of 830 front panels that had both HF and SSB, and then realized that by that time SSB had become pretty standard and they did not need to include it. When the earlier rigs were made, SSB was not yet so standard so they would want to point it out.

I usually take the "if it ain't broke don't fix it" approach. The only electrolytic cap in this amplifier is the 4.7 uf output cap. If you want to replace it, it won't hurt but I have not seen a lot of these fail. Be sure to have the replacement installed with the correct polarity.

Impedance matching of the amplified stand to the Kenwood is not an issue. Since the element is isolated from the radio by the amplifier, and the amplifier has plenty of gain, the impedance is unimportant.

My modification to a FET amplifier loads the element at a even higher impedance than the original amplifier giving the element an even more full sound.

The amplified D-104 works well with Kenwood hybrids.

Subject: [TS-520_820_530_830] D-104 Question

I have a 520S and a 530S. Will a D-104 with the amplified T-UG8 stand match up with these radios as far as impedance goes? I read where the amp was an attempt to match the old crystal element to the newer radios. Also, would it be a good idea to replace the electrolytic caps on the amplifier of this mic?

Hi all,

Hope to get an answer or two on this post.

Three odd things are happening on the TS-830 that I am restoring.

1. The drive from the MC-50 seems very low. I have to have the mic gain up at around 2pm (7 on the dial) AND the processor in at about 2pm (minimum) on it's gauge just to get around 45w peak talk power on my external meter.

It tunes at 100w - 120w CW no problem.

2. Although I get a reasonable level CW sidetone, I get no SSB monitor on audio out using the "MONI" button.

3. The receive on 18Mhz band is intermittent, where it drops at least 3-4 s-points randomly.

Hope I can be pointed in the right direction.

Thank you all.

Bruce: Would you please e-mail me the article? 73, Chuck, WA4IIF

In a message dated 1/19/2011 4:10:51 P.M. Central Standard Time,
w8hw@... writes:

In general, there are two types of notch filters... Automatic and Manual notch filters. Regardless of type a notch filter is the opposite of a Band Pass filter. A Notch filter takes out (notch) one frequency while allowing all other frequencies to pass. An example of the use of a automatic notch filter is on SSB. If you are speaking to your ham friend using SSB and someone transmits a STRONG carrier on your frequency, it can nock out your friends signal until you engage your ANF (Automatic Notch Filter). The ANF will try to seek out the frequency that the carrier is on and "Notch" it out leaving only your friends voice.

ANF can NOT be used while operating CW or Digital because a ANF could and will destroy the very single frequency that you are trying to listen to. ANF must be turned off while using those modes. You may use a manual notch filter if needed. This is because it is manual, you can set it on a frequency that you do not wish to listen to (interfering signal) and it will not seek the signal that you wish to listen to.

Above is the short and quick answer. I have an article that is about filtering in general. Many people have requested it. If you wish to have it emailed to you, send me a email and I will send it to you. Hope that this helps.

Hello Chris,

First, the CW sidetone does not flow through the same circuit as the transmit "MON" audio does.

MON transmit audio is produced by sampling the transmit IF signal through a simple detector circuit and applying the detected audio to the audio amplifier. CW sidetone audio is applied directly to the receive audio amplifier.

Normal non-processed transmit audio with the MIC gain set between 10 and 11 o'clock will produce an average power output displayed on an average watt meter between 20 and 30 watts. If this is what you see then there's nothing wrong with your 830. Folks tend to believe it the transmitter is not producing 100 watts on a watt meter then there's something wrong. That's not true. Most watt meter are average watt meters which will not display 100 watts output in sideband but rather between 20 and 30 watts peak output on an average watt meter.

Also, if tuning the 830 up produces 100 watt output in CW mode then there is nothing wrong with the 830s ability to produce full output.

As for intermittent receive on 18Mhz, this could be caused by a dirty band switch wafer. Try cleaning the band switch wafers, don't forget the wafer switch inside the final amplifier enclosure, with contact cleaner. Apply a small amount of cleaner to the wafer switches, rotate the switch completely CW and CCW, a number of times then use canned air to remove any/all cleaner residue. Wait a few minutes (3 - 5 minutes) and test for proper operation. All contact cleaning process should be done with the transceiver tuned OFF, NEVER with the transceiver turned ON! Contact cleaner is flammable and it only takes a small spark to ignite the cleaner. Adhere to all warnings on the can of cleaner.

" I recommend pulling the PLL Unit and checking each 10 meter VCO crystal on the PD Unit to ensure the crystals for all 10 meter positions have the same frequencies listed above. If the 10 meter VCO crystal are "lower" in frequency then a previous owner had the 820 modified to operate on 11 meters or a frequency band other than the ham bands."

Good Morning Mike, I have been studying your email and my downloaded service manual, and a lot of Google surfing all weekend, and was wondering if you would mind answering a couple questions for me. To access the 10 meter crystals on the PD unit, do I just carefully remove the 4 corner brass hex nuts you can see in the picture, and then the board will carefully pull out. Are the crystals located on the back of this printed circuit board, under their prospective adjustment points, that is held in by the 4 hex nuts in the corners.
As none of my digital VM's read anything close to 35 MHz in the frequency mode, I am going to have purchase an inexpensive frequency counter kit online, make it and then use it to test the crystals. I am in for a real education aren't I, by the time I get everything right, and or figured out, and then get my upgrade to general next month, I will eventually be able to key up with a real big smile on my face. HA LOL,,,,,,, Thanks for your continued help. Just cause I have been fabricating and welding for almost 35 yrs doesn't mean I cant learn some new tricks, Right. !! Thanks again Blake KF7HHC

Subject: [TS-520_820_530_830] Re: TS-820 with Digital display, 10 meter display fluctuating and wont stop.

Hello Joe and Blake,

If the PLL Unit become unlocked, for what ever reason, the digital display will be dark, nothing displayed, and both transmit and receive will fail.

TC1 on the IF Unit sets the level of the CAR Unit signal to the digital display. Adjusting TC1 will not fix the problem you are experiencing on 10 meters. Although the CAR Unit signal is used on all bands, the CAR Unit signal is not band specific, meaning there isn't a different CAR signal for each band. Adjusting TC1 on the IF Unit will not fix the problem you are experiencing on 10 meter. Adjusting TC1 will affect ALL bands simultaneously as you have found out.

The problem you are experiencing on 10 meters appears to be an improperly adjusted VCO Unit 10 meter (all 10 meter settings) VCO Oscillator in the PLL Unit. The VCO Unit adjustments are covered on page 52 of the 820 service manual under "Adjustment of VCO unit". Table 2 on

page 53 lists all of the VCO oscillator frequencies and each VCO oscillator coil. The 10 meter VCO oscillator coils are T7 thru 10.

Each band has an individual VCO crystal that is selected by the band switch. The 10 meter VCO crystals are located on the PD Unit and their individual crystal frequencies are as follows:

28.0 = 33.5Mhz
28.5 = 34Mhz
29.0 = 34.5Mhz
29.5 = 35Mhz

I recommend pulling the PLL Unit and checking each 10 meter VCO crystal on the PD Unit to ensure the crystals for all 10 meter positions have the same frequencies listed above. If the 10 meter VCO crystal are "lower" in frequency then a previous owner had the 820 modified to operate on 11 meters or a frequency band other than the ham bands.

Topic: 29670 Message: 29690

Morning Blake,

The PLL Unit is located on the bottom of the 820. There are 4 screws on the top 4 corners of the PLL Unit that must be removed. There are also 2 additional screws, accessed through 2 holes on the side of the chassis (820 up side down and front panel facing you) that also must be removed. Also remove the plugs connecting the PLL Unit to the wiring harness. Remove the side screws first, the wiring harness plugs next, then the 4 corner screws and the PLL Unit should lift out. Use caution when removing the wiring harness plug, you don't want to break any of the plug wires. Since this is your first time removing a module, pay attention to where the wiring harness plugs are plugged into the PLL Unit. While the plugs will generally fall next to the pins they connect to, it's always good to make a mental and/or drawing of where the plugs do so when reinstalling the PLL Unit you put the plugs back onto the right points. Make sure you do not twist the plugs 180 degrees when inserting them. They are somewhat "sailor proof", meaning they only plug in one way but just be cautious to ensure they are plugged in correctly.

Installing the PLL Unit back into the 820 simply reverse the removal steps except install the plugs "last".

There are 2 PC boards inside the PLL Unit, the "PD" and "VCO" boards. The individual band switch selected VCO oscillator crystals are mounted on the component side of the "PD Unit" PC board. They are small, about the size or slightly smaller than a "chicklet" candy, but thinner. The frequency of each crystal is typically stamped on the top of the crystal. Compare the stamped frequency on top of the crystal to the crystal frequencies shown on the PD Unit schematic in the 820 service manual page 64. The crystals are labeled "X6 thru X10" connected to the base terminals of transistors Q6 thru Q10 on the PD Unit schematic. Once the PLL Unit is removed, remove the metal enclosure screws holding the metal cover. At this point you can look at the crystals on the PD Unit board and determine whether the all of the crystal are the frequencies they should be.

While you have the PLL Unit out of the 820, clean the internal pins and sockets that connect the 2 boards together inside the metal enclosure. Remove the boards, one at a time, and clean the pins and sockets on the board using contact cleaner. Insert and remove the board a few times to allow scrubbing action to clean the pins and sockets. Do this one board at a time then install the board back into the metal case and secure the board with the mounting screws. Use canned air to remove any and all cleaner residue. Repeat the cleaning process with the other board. Make sure you remove any/all cleaner residue with canned air (available a Walmart) before you reassemble the PLL Unit and install it back into the 820.

29691. A question regarding tuning a TS520

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-07 17:46:25 UTC
From: Simon Taylor
Topic: 29691 Message: 29691

Hi everyone,

I am enjoying being a member of this group and have recently taken ownership of a TS520 and like many new to hybrids, I have a question regarding the tune-up proceedure, in particular 'drive tuning'.

Having ensured that the circut bias is adjusted to 60 ma, the instruction maunal suggests the following in regards to 'drive tuning':

'Shift the METER switch to ALC and the MODE switch to TUN and peak the ALC reading (maximum meter deflection) with the DRIVE control.'

MY QUESTION THEREFORE IS THIS:
By maximum meter deflection, does it mean maximum within the ALC reading on the meter, or Maximum reading on the meter, which is obviously greater than the ALC reading?

I know I may appear a little dim, but want to ensure that I look after this lovely lady and enjoy her outstanding performance.

I look forward to any thoughts you can give me.

Thanks,

Simon

Hi Simon,

You tune for outright maximum (max meter deflection) in the tune position. The much smaller range is for adjustment of mic gain in SSB mode to keep the finals operating in the cormect range (no positive grid current).

Greg

Thanks Mike. Yes I realise that the CW sidetone is different and fed through the AF.

The MONI button turned on should give me a sampled SSB audio though and doesn't.

The average PO on my LDG AT1000 is around 15-20 watts on SSB... So a little low I guess.

Good points re the 18Mhz band... Will take a look at the wafers tonight.

Thanks again.

> Normal non-processed transmit audio with the MIC gain set between 10 and 11 o'clock will produce an average power output displayed on an average watt meter between 20 and 30 watts. If this is what you see then there's nothing wrong with your 830. Folks tend to believe it the transmitter is not producing 100 watts on a watt meter then there's something wrong. That's not true. Most watt meter are average watt meters which will not display 100 watts output in sideband but rather between 20 and 30 watts peak output on an average watt meter.
>
> Also, if tuning the 830 up produces 100 watt output in CW mode then there is nothing wrong with the 830s ability to produce full output.
>
> As for intermittent receive on 18Mhz, this could be caused by a dirty band switch wafer. Try cleaning the band switch wafers, don't forget the wafer switch inside the final amplifier enclosure, with contact cleaner. Apply a small amount of cleaner to the wafer switches, rotate the switch completely CW and CCW, a number of times then use canned air to remove any/all cleaner residue. Wait a few minutes (3 - 5 minutes) and test for proper operation. All contact cleaning process should be done with the transceiver tuned OFF, NEVER with the transceiver turned ON! Contact cleaner is flammable and it only takes a small spark to ignite the cleaner. Adhere to all warnings on the can of cleaner.

Simon and Greg,

Greg is correct, tune for maximum meter indication, not just within the ALC scale.

Greg, when ALC is indicated on the meter (meter switch set to ALC) during TUNE mode (DRIVE control adjusted for peak indicattion) and during normal sideband transmissions, the grids are already swinging "positive".

ALC is produced when grid current starts to flow in the final tubes. The more positive the final tube grids swing the more ALC voltage is produced.

The amount/level of ALC produced depends on the amount of "positive" swing of the grids in the final amplifier tube. This is all controlled by the level of RF output signal applied from the driver tube to the grids of the final tubes. If a portion of the positive half of the RF sine wave level from the driver tube is at a level that causes the grids of the final tubes to swing "positive" then a current between the final tube cathodes and grids exist. This induces a voltage that is sensed by the ALC amplifier transistor resulting in a "difference of potential" between the ALC amplifier transistors Base and Emitter. This difference of potential results in a change in the ALC amplifier transistors Collector voltage. The varying ALC amplifier Collector voltage is now the "ALC" voltage that is fed back to the IF Unit's IF amplifier to "reduce" the IF amplifiers gain which "reduces" the RF output of the transceiver. Transmitter ALC functions the same way a receiver's AGC does, controls the gain.

When ALC is produced (grid current flowing in the final tubes), power is consumed in the final tube grids which reduces the power output at the final tube plates circuit. In addition, when grid current flows in the final tubes the output signal becomes distorted since the final tubes are no longer operating in their linear state. The final amplifier in the hybrids operate in Class AB1. Class AB1 amplifier "normally" do not have grid current flowing throughout the sine wave cycle. The purpose of ALC is to bring the amplifiers back into their linear state and it accomplishes this by reducing the gain of the earlier "IF" stage. By reducing the gain of the IF amplifier the overall gain of the transmitter is also reduced resulting in reduction in RF output from the final amplifier.

One more comment.

The reason Kenwood uses the ALC meter setting in TUNE mode is because ALC has a more pronounce peak than the IP position does. The IP meter setting does show a peak BUT it will not show the "actual" peak when it occurs. The IP meter setting is more "flat" or once the IP meter peaks, any further adjustment which would cause a reduction in ALC or slight increase in ALC would not be seen in the IP setting. So to see the true peak in grid current based on the peak signal from the driver tube through adjusting the DRIVE control, the ALC meter setting is used.

In older transmitters with a "grid" meter setting, transmitters were tuned for "maximum grid drive". This meant the driver was tuned for a maximum RF signal applied to the input of the final amplifier. The "grid" meter actually displays grid current in the final tubes NOT the driver tube. The same applies in the Kenwood hybrids, ALC is indicating maximum RF drive to the final amplifier by displaying the level of ALC produced by the maximum grid current flowing in the final tube grids.

Dick,

Welcome to the world of KW hybrids. Check the "DUH FACTOR" first. I am guilty of this myself.....check that the "RF GAIN" control is fully CW...and/or the "SEND/RCV" switch is not in "SEND" I am still working on a 520 that had a CB HACK. Whom ever was in there really messed it up...I think Gordon(N6WK) who is in the group..is not too far from you...GOOD LUCK.....

Topic: 29700 Message: 29700

Hi Folks,

I have come accross a AT-200 which will go nicely with my TS520. However.

The 2 Diodes in the SWR circuit are dead and I can't find replacements
listed anywhere in ZL.

Does any one out there know what the equivelent is for the 2 diodes are they
are listed as 2-1K261
If anyone has any advise please help.

73

Alan

They ate NTE110 diodes. Very common
Here are the specs
http://www.nteinc.com/specs/100to199/pdf/nte110mp.pdf

Blake,

Check out the photo section of this group, I think it's under TS-820(S) CB HACK...by wb7uqu. I took apart the "PLL BOX", photographed the "PD BOARD" out of the "PLL UNIT" It shows the crystals that are very commonly replaced with lower MHz crystals of usually 1.5MHz - 2.0 MHz lower in the positions of X9 & X10. Most times they will jump out at you because the are all silver and do not have the blue plastic "shrink-wrap" around them with the frequency printed. I have seen however, crystal "cans" as described by Mike. What's important is that the correct frequencies are in the correct places. Also...get yourself a "HIGH -RES" "xray" view of the PD board...and check ALL the foil traces. It's a real pain in the arse...but I found 1 of the boards had been very badly soldered by the hacker...and spent way too much time trying to figure out what was wrong. Found some poor solder work, causing a couple of "solder bridges." Good luck.....

Subject: [TS-520_820_530_830] Re: TS-820 with Digital display, 10 meter display fluctuating and wont stop.

Morning Blake,

The PLL Unit is located on the bottom of the 820. There are 4 screws on the top 4 corners of the PLL Unit that must be removed. There are also 2 additional screws, accessed through 2 holes on the side of the chassis (820 up side down and front panel facing you) that also must be removed. Also remove the plugs connecting the PLL Unit to the wiring harness. Remove the side screws first, the wiring harness plugs next, then the 4 corner screws and the PLL Unit should lift out. Use caution when removing the wiring harness plug, you don't want to break any of the plug wires. Since this is your first time removing a module, pay attention to where the wiring harness plugs are plugged into the PLL Unit. While the plugs will generally fall next to the pins they connect to, it's always good to make a mental and/or drawing of where the plugs do so when reinstalling the PLL Unit you put the plugs back onto the right points. Make sure you do not twist the plugs 180 degrees when inserting them. They are somewhat "sailor proof", meaning they only plug in one way but just be cautious to ensure they are plugged in correctly.

Installing the PLL Unit back into the 820 simply reverse the removal steps except install the plugs "last".

There are 2 PC boards inside the PLL Unit, the "PD" and "VCO" boards. The individual band switch selected VCO oscillator crystals are mounted on the component side of the "PD Unit" PC board. They are small, about the size or slightly smaller than a "chicklet" candy, but thinner. The frequency of each crystal is typically stamped on the top of the crystal. Compare the stamped frequency on top of the crystal to the crystal frequencies shown on the PD Unit schematic in the 820 service manual page 64. The crystals are labeled "X6 thru X10" connected to the base terminals of transistors Q6 thru Q10 on the PD Unit schematic. Once the PLL Unit is removed, remove the metal enclosure screws holding the metal cover. At this point you can look at the crystals on the PD Unit board and determine whether the all of the crystal are the frequencies they should be.

While you have the PLL Unit out of the 820, clean the internal pins and sockets that connect the 2 boards together inside the metal enclosure. Remove the boards, one at a time, and clean the pins and sockets on the board using contact cleaner. Insert and remove the board a few times to allow scrubbing action to clean the pins and sockets. Do this one board at a time then install the board back into the metal case and secure the board with the mounting screws. Use canned air to remove any and all cleaner residue. Repeat the cleaning process with the other board. Make sure you remove any/all cleaner residue with canned air (available a Walmart) before you reassemble the PLL Unit and install it back into the 820.

Hi Gordon.

Thank you very much for your reply.

secondly I have also been trying to find a replacement for the 520 DC-DC converter transistors without any luck

Q1 and Q2 T20A6 or 2N2049.

Thanks again

Alan

Alan,
You can download the NTE cross reference software from here:
http://nte01.nteinc.com/webforms.nsf/qcsignin?openform

Just fill out the form and then download and install it.
I have been using it for years and find it is great!

73,
Gordon

Well, I typed in 2N2049 as you first asked and it comes up to a NTE123AP.
But now you typed 2N2019... that's different. Which one are you looking for?

Gordon

Alan,
I just checked for the Specs Converter.
Q1 and Q2 are *2N4049* which crosses to a NTE28

Gordon

It shows it as an NPN

Topic: 29710 Message: 29710

Circumstances dictate that I must sell one of my most prized possessions.
This 830 was purchased in Singapore at Caltron LTD. by a US govt. radio engineer in 1982. It was used for a very short time there and then sent to Bethesda MD in it's original boxes never to be used again.(it does have it's transformer wired for 120v) I bought it from that individual(now SK). It is in pristine condition with manual and correspondence between the original owner and Kenwood/Trio (concerning wiring for 120v). There are absolutely NO scratches, mars, dents, rust, etc. I doubt that a more perfect example exsists anywhere. (other than a complete k4eaa rebuild. lol)
No, I have never powered it up, it has stayed in it's box, I use my other 830. It has the YK88S1 ssb crystal. I am going to offer it here first for a day or two and then on eham. I want $525 for it, plus shipping. I will accept PayPal or a US postal money order. Contact me at gmichaelb@... or 928-716-7788

OOPS...

I just checkd my stock and I have RG-179 cable (75 Ohm) available in bulk and not the RG-174 (50 Ohm) that I thought I had. You might be able to use that since it's such a short amount.

I do have one piece of RG-174 that is 31 inches long, I'll send that and 10 feet of the RG-179 if that helps...

No charge.

hi Alan,

have you asked KE5FTF Bob if he has them?

http://www.eham.net/classifieds/detail/334405

another solution is to power the radio using
a full sine wave ups, like the apc smartups series,
you can autostart it directly from battery without ac available.
they are cheap without the batteries on ebay.

Just add powerpole and fuses to a larger external battery
and you're good to go.

29714. tuing coil installation

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-08 04:43:07 UTC
From: kevin
Topic: 29714 Message: 29714

Is it possible to remove and replace the 28Mhz tuning coil from board X40-0017-00 in a 520 without removing the board? Mine looks like someone dripped solder into it. I have a donor radio.

Also did I understand from an earlier post that if you remove a board that is attached by wires which are tightly "wound" around contact posts that it is good form to solder the lead to the post when re-installing?
Best Regards,
Kevin

Hey Kevin, don't take this the wrong way, but it really depends on your soldering skills. If you're comfortable with doing it and have the right tools then it's no problem at all. You just need to remove the metal shield between the Antenna Coil Board and the Driver Coil Board so that you can reach the solder side of the Driver Coil Board.

I had a similar situation with the Antenna Coil Board where I had to remove L1 to re-wrap it. I used wicking brade to not only to remove the solder, but to relieve the joint of some of the heat as well. If you apply too much heat for too long you can lift the trace or push the post through the coil form so you do need to be careful.

Mine was a bit tricky because whoever installed the components bent all 4 leads to the coil instead of just the two that you would need to hold the coil in place long enough to solder it in so I had to desolder the connections, straighten out the leads, and then gently pry the coil out of the holes from the underside of the coil form with a miniature flat head screwdriver.

It took about 30 minutes from start to finish but it worked out pretty well.

It would probably be just as easy and less labor intensive to just switch out the whole board and if you decide to go that route then yes you should clean all of the connections, tin them, and then solder them to make your connections. The posts I was working with were heavily oxidized and solder doesn't play well with oxidation.

Hope this helps.

73!

Hi

A friend gave me a Bencher YA-1 LPF and I intend using it with my TS520SE.

All markings (except manufactures label) are not visible in the LPF.

I want to know which side should I connect to TX.

Appreciate any help

Connect the side that is closest to the TX...

(It shouldn't matter, they are built symetrical).

Blake,

Check out the photo section of this group, I think it's under TS-820(S) CB HACK...by wb7uqu. I took apart the "PLL BOX", photographed the "PD BOARD" out of the "PLL UNIT" It shows the crystals that are very commonly replaced with lower MHz crystals of usually 1.5MHz - 2.0 MHz lower in the positions of X9 & X10. Most times they will jump out at you because the are all silver and do not have the blue plastic "shrink-wrap" around them with the frequency printed. I have seen however, crystal "cans" as described by Mike. What's important is that the correct frequencies are in the correct places. Also...get yourself a "HIGH -RES" "xray" view of the PD board...and check ALL the foil traces. It's a real pain in the arse...but I found 1 of the boards had been very badly soldered by the hacker...and spent way too much time trying to figure out what was wrong. Found some poor solder work, causing a couple of "solder bridges." Good luck.....

Subject: [TS-520_820_530_830] Re: TS-820 with Digital display, 10 meter display fluctuating and wont stop.

Morning Blake,

The PLL Unit is located on the bottom of the 820. There are 4 screws on the top 4 corners of the PLL Unit that must be removed. There are also 2 additional screws, accessed through 2 holes on the side of the chassis (820 up side down and front panel facing you) that also must be removed. Also remove the plugs connecting the PLL Unit to the wiring harness. Remove the side screws first, the wiring harness plugs next, then the 4 corner screws and the PLL Unit should lift out. Use caution when removing the wiring harness plug, you don't want to break any of the plug wires. Since this is your first time removing a module, pay

attention to where the wiring harness plugs are plugged into the PLL Unit. While the plugs will generally fall next to the pins they connect to, it's always good to make a mental and/or drawing of where the plugs do so when reinstalling the PLL Unit you put the plugs back onto the right points. Make sure you do not twist the plugs 180 degrees when inserting them. They are somewhat "sailor proof", meaning they only plug in one way but just be cautious to ensure they are plugged in correctly.

Installing the PLL Unit back into the 820 simply reverse the removal steps except install the plugs "last".

There are 2 PC boards inside the PLL Unit, the "PD" and "VCO" boards. The individual band switch selected VCO oscillator crystals are mounted on the component side of the "PD Unit" PC board. They are small, about the size or slightly smaller than a "chicklet" candy, but thinner. The frequency of each crystal is typically stamped on the top of the crystal. Compare the stamped frequency on top of the crystal to the crystal frequencies shown on the PD Unit schematic in the 820 service manual page 64. The crystals are labeled "X6 thru X10" connected to the base terminals of transistors Q6 thru Q10 on the PD Unit schematic. Once the PLL Unit is removed, remove the metal enclosure screws holding the metal cover. At this point you can look at the crystals on the PD Unit board and determine whether the all of the crystal are the frequencies they should be.

While you have the PLL Unit out of the 820, clean the internal pins and sockets that connect the 2 boards together inside the metal enclosure. Remove the boards, one at a time, and clean the pins and sockets on the board using contact cleaner. Insert and remove the board a few times to allow scrubbing action to clean the pins and sockets. Do this one board at a time then install the board back into the metal case and secure the board with the mounting screws. Use canned air to remove any and all cleaner residue. Repeat the cleaning process with the other board. Make sure you remove any/all cleaner residue with canned air (available a Walmart) before you reassemble the PLL Unit and install it back into the 820.

Topic: 29722 Message: 29722

Just wanting to know if anyone elses radio is missing r13 on the rf board. This is the 2nd resistor I've found that is missing from the radio and looks to be missing from the factory looking at the board. I do see it in the component schematic and it shows where resistor is supposed to be. But in the circuit schematic it doesn't appear to be there. I can tell where it is supposed to be in the circuit but isn't there. thanks, nathan

29723. Re: r13 on rf board?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)

What model (520, 530, 820, or 830) transceiver and what board are you referring to where R13 is missing?

Kenwood appears to have more than one "version" of board(s) in the hybrids. The important thing is to make sure the number on the foil side of the board is compared with any replacement board you use. I recently replaced the AF AVR Unit board in my 820. I ordered a replacement board and when it arrived I installed it. Everything worked except there was no audio output. My first thought was the audio chip on the board had failed. However, after closer inspection, comparing the original board with the replacement board I notice there were components on the replacement board that were not present on the original board. Looking further I notice the foil side had a number. I compared the numbers on both boards. The number on the original AF AVR Unit board had a different suffix number than the replacement board had. The original board had "J25-1381-13" but the replacement board had "J25-1381-03". The difference turned out to be the circuit foil design to the pins for plug AF3 were different than the circuit foil design to the pins for plug AF3 on the original board.

For 820 owners, if you look at the 820 service manual, page 57, you will see the AF AVR Unit schematic AND the xray component image. Look closely at the xray component image and you will clearly see "J25-1381-03". If you look at the schematic and compare the AF3 plug pins to the xray image you will clearly see they are different. That means the AF AVR Unit schematic on page 57 is NOT the schematic for the xray image shown on page 57 of the 820 service manual. One of the 820 operators manuals on page 31 shows the schematic for the "J25-1381-03" AF AVR Unit board. If you have the 820 operators manual, look at the bottom of the last page. There's a number
B50-2529-00. The AF AVR Unit schematic on page 31 is for the "J25-1381-13" board. The other 820 operators manual, last page, has a number B50-1558-00 and the AF AVR Unit schematic on page 31 is the schematic for the "J25-1381-03" board.

I also replaced the RF Unit board in my 820. The foil side numbers were the same BUT, the original board had components added on the foil side that were not present on the replacement board. The original board had a 47 ohm 1/4 watt resistor between "S" terminal and ground on Q2 (receiver RF amplifier) and a pair of germanium diodes wired back to back from the "RG" plug terminal to ground. These components were not present on the replacement board. I have not found any service bulletins or modifications that discuss these additions. I can only determine their purpose by how they are installed. The 47 ohm resistor between Q2s "S" (Source) terminal and ground reduces the gain of the RF amplifier while the back to back diodes between the "RG" plug terminal and ground acts to suppress static surges from the antenna connector, protect Q2. The gain in the replacement RF Unit is clearly higher than the original RF Unit board.

Therefore, you should look closely at the schematic, xray component image, and the board itself to ensure the schematic, image, and board are the same.

Bob and Peter,

Attachments are not allowed when responding to posts. That's why Peter didn't see the manual.

The FL-2100B operators manual can be downloaded at the following link

http://www.bcdxc.org/fl2100b_man.pdf

The FL-2100B rear panel has screw terminals for relay and ALC connections. The amplifier terminals labeled "E" are "ground". The relay is labeled "RY" and ALC is labeled "ALC".

A 7 pin DIN plug is required and the DIN plug is wired as follows:

DIN plug pin 2 is connected to the amplifier's "RY" terminal and DIN plug pin 4 is connected to the amplifier's "E" terminal.

DIN Plug pin 6 is connected to the amplifier's "ALC" terminal.

That is all there is to connecting the FL-2100B control lines to the TS-830 REMOTE DIN socket. The FL-2100B relay voltage is approximately 12VDC and the current is around 100ma. Therefore, you do not need an amplifier interface between the 830 and the FL-2100B amplifier.

If the amplifier has straps between "RY" and "E" terminals, remove the straps.

Yes. I see I misread the original subject, TS-820.

Connect the FL-2100B "RY" terminal to the 820 rear 8 pin octal socket pin 5 and the FL-2100B "E" to the rear 8 pin octal socket pin 1 or pin 4 (ground). Connect the FL-2100B "ALC" terminal to the 820 8 pin octal socket pin "6".

Sorry for the misread.

The first response I gave contained the connection instructions for the TS-830. The second response was for the TS-820.

If you do not have an 8 pin octal plug for the TS-820 rear 8 pin octal socket you can an 8 pin male octal plug from Radio Daze, www.radiodaze.com for a couple of dollars.

There is no mystery with the Yaesu FL-2100B amplifier. The FL-2100B will work with any of the Kenwood hybrids.

The control connections, relay and ALC, are all straight forward and easy to connect. Depending on the exciter/transceiver used, whether it's a TS-520 series, TS-820 series, TS-530, or TS-830, determines what REMOTE socket plug is required. The TS-520 and TS-820 series requires an 8 pin male octal plug while the TS-530 and TS-830 requires a 7 pin "DIN" plug. The relay and ALC connections are shown in each exciter/transceiver manual.

The amplifier relay connection is made to the exciter/transceiver's "Normally Open" relay terminals in the exciter/transceiver's rear panel REMOTE socket whether it be 8 pin octal or 7 pin DIN sockets. Again, these are shown in the exciter/transceiver's operator's manual.

The amplifier "RY" (Relay), "ALC", and "E" (ground) terminals are easy to use. Simple shield cable such as those cheap stereo inter-connecting cables used to connect VCR, DVD, and stereo amplifiers can be used. The FL-2100B relay voltage and current ratings are 13VDC at about 100ma. There is no need for an expensive and useless amplifier relay interface between the FL-2100B and hybrid exciter/transceiver.

The FL-2100B amplifier operators manual can be downloaded FREE, on the Internet, by simply entering "FL-2100B manual" into your favorite search engine, "Google", "Bing" etc, as the search phrase and up comes the link:

http://www.bcdxc.org/fl2100b_man.pdf

Yes, I know the FL-2100B ALC output is not adjustable. However, a simple variable resistor/pot can be added to make this possible. This will allow you to vary the maximum level of ALC applied from the FL-2100B to the exciter/transceiver's REMOTE socket ALC connection in the same fashion as a volume control does in an audio amplifier. One terminal of the pot is connected to the amplifier's ALC terminal, the other pot's terminal is connected to ground "E" and the pot's "WIPER" (center pin) is connected to the exciter's REMOTE socket's ALC terminal. The pot is adjusted for zero or minimum ALC output voltage as measured with a simple DVM. The SSB signal is applied to the amplifier and the pot is adjusted until the power output from the amplifier starts to reduce or the maximum ALC voltage rating of the exciter has been achieved. This is similar to how Ameritron's AL-811 and AL-811H rear panel ALC pot is used. The Ameritron AL-811 and AL-811H ALC output gain control voltage is actually rectified "exciter/transceiver" RF drive. The rectified ALC voltage is then applied to the AL-811 or AL-811H rear panel ALC pot where the pot regulates, based on its setting, the level of ALC gain control voltage that is applied back to the exciter/transceiver, same as what I mentioned above.

One additional comment. There is no need for diodes when using the simple ALC adjustable pot circuit I mentioned because the FL-2100B already rectifies the ALC voltage. That means the voltage at the FL-2100B "ALC" terminal is "DC", not "RF".

I initially uploaded a file that shows a simple variable ALC circuit for the Yaesu FL-2100B amplifier. The original file was produced using Windows 7 Office intro. Unfortunately that file may not be compatible with XP Windows Word, it has a ".docx" suffix. I have since uploaded the same file in pdf format which can be viewed using the Adobe Acrobat reader.

The circuit is what Ameritron uses in their variable ALC output in the AL-811 and AL-811H amplifiers. I see no reason it will not work with the FL-2100B amplifier. The circuit can be built either inside the amplifier or in an external small metal box. There are only 3 components, 2 fixed resistors and one variable resistor.

That's good. I don't have an XP machine to check. My machine is a 64 bit Windows 7 with Windows Office intro. Anyway, glad to see XP office converted it.

Unfortunately that file may not be compatible with XP Windows Word, it has a ".docx" suffix. I have since uploaded the same file in pdf format which can be viewed using the Adobe Acrobat reader.
>
> The circuit is what Ameritron uses in their variable ALC output in the AL-811 and AL-811H amplifiers. I see no reason it will not work with the FL-2100B amplifier. The circuit can be built either inside the amplifier or in an external small metal box. There are only 3 components, 2 fixed resistors and one variable resistor.

Hi Mike,

One more question.

Can I use the CAR control on the TS-830S to reduce the power I need to drive the Fl-2100B?

I dont want to drive the amp at full input power

73

Depending on the exciter/transceiver used, whether it's a TS-520 series, TS-820 series, TS-530, or TS-830, determines what REMOTE socket plug is required. The TS-520 and TS-820 series requires an 8 pin male octal plug while the TS-530 and TS-830 requires a 7 pin "DIN" plug. The relay and ALC connections are shown in each exciter/transceiver manual.
> >
> > The amplifier relay connection is made to the exciter/transceiver's "Normally Open" relay terminals in the exciter/transceiver's rear panel REMOTE socket whether it be 8 pin octal or 7 pin DIN sockets. Again, these are shown in the exciter/transceiver's operator's manual.
> >
> > The amplifier "RY" (Relay), "ALC", and "E" (ground) terminals are easy to use. Simple shield cable such as those cheap stereo inter-connecting cables used to connect VCR, DVD, and stereo amplifiers can be used. The FL-2100B relay voltage and current ratings are 13VDC at about 100ma. There is no need for an expensive and useless amplifier relay interface between the FL-2100B and hybrid exciter/transceiver.

> > Yes, I know the FL-2100B ALC output is not adjustable. However, a simple variable resistor/pot can be added to make this possible. This will allow you to vary the maximum level of ALC applied from the FL-2100B to the exciter/transceiver's REMOTE socket ALC connection in the same fashion as a volume control does in an audio amplifier. One terminal of the pot is connected to the amplifier's ALC terminal, the other pot's terminal is connected to ground "E" and the pot's "WIPER" (center pin) is connected to the exciter's REMOTE socket's ALC terminal. The pot is adjusted for zero or minimum ALC output voltage as measured with a simple DVM. The SSB signal is applied to the amplifier and the pot is adjusted until the power output from the amplifier starts to reduce or the maximum ALC voltage rating of the exciter has been achieved. This is similar to how Ameritron's AL-811 and AL-811H rear panel ALC pot is used. The Ameritron AL-811 and AL-811H ALC output gain control voltage is actually rectified "exciter/transceiver" RF drive. The rectified ALC voltage is then applied to the AL-811 or AL-811H rear panel ALC pot where the pot regulates, based on its setting, the level of ALC gain control voltage that is applied back to the exciter/transceiver, same as what I mentioned above.

Peter,

No. The MIC gain controls the RF output in USB and LSB modes. The CAR control has absolutely no control what so ever over RF output in USB or LSB modes! The CAR control has control over RF output in TUNE and CW modes ONLY!

ALC, a gain control voltage, that is produced when grid current flows in the final tubes, also controls RF output but ONLY when ALC is produced.

Don't believe when someone tells you that the ALC meter must always peak at the top of the ALC scale. That's NOT true! ALC, when produced, "reduces" RF output NOT increases RF output!

Just remember, ALC works in a transmitter the same way AGC works in a receiver, to control gain, period! The leter "A" in ALC stands for "Automatic", the "L in ALC stands for "Level" and the "C" stands for "Control". Put them together and ALC stands for "Automatic Level Control"!

I have a brand New in package part number L34-2004-05 coil for the Kenwood TS-830S. It is L41 on the RF board. The 160 meter coil that always burns out.
Asking $20.00 plus $2.00 shipping
Was going through my parts cabinet and came across it.
thanks,
Gordon
N6WK

29749. TS-830 receive and transmit loss

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-11 11:34:40 UTC

Topic: 29749 Message: 29749

Hello dear fellow hams,

my TS-830 has a strange fault; from one to the other moment it has a drop in receive and it does not transmit anymore.
When hitting the send switch it shows approx 60mA of bias, but i can't tune or get any output out of the rig. Also the receiver shows only very low signals.

I suspected the RL-1 relay and replaced it, but that was the the cause of this fault.

Maybe one of you has an idea where to search or check?

thanks in advance, 73's Ton pa1pxl

You said you replaced RL1 which I assume is RL1 on the AF Unit. You also said that RL1 is now the cause of your current low receive and no RF output.

I recommend you visually inspect the solder connections at the foil side of the relay pins and the foil runs to the relay pins. The foil on the PC boards are very thin and are easily broken/cracked by heat when soldering or desoldering. A broken foil run can affect the circuits the relay controls (receiver biasing, driver and both final tube biasing, and switching between receive and transmit).

A method I use to inspect for cracked or broken PC board foil runs is shinning a bright light on the component side of the board while looking through a magnifying glass on the foil side. The light will clearly show defective/broken/cracked foil runs.

I replaced that same relay in a TS-120 I recently worked on. When I completed the replacement I found the S meter did not work. The S meter circuit flows through one set of relay terminals. I used the method described above and found the foil to one of the relay pins was broken/cracked, opening the S meter circuit. I fixed the broken foil run and the problem was solved, the S meter worked.

One additional comment.

I mentioned in my recent response that the relay on the AF Unit control receiver biasing and switching between receive and transmit. RL1 on the AF Unit controls the biasing of receiver RF amplifier Q1 on the RF Unit over the "RB1" line. If the pins of the relay on the foil side are not making good contact due to a broken or cracked foil at the relay pin then the "RB1" voltage will be missing at the RF Unit. RB1 voltage flows from AF unit plug 6 pin through the wiring harness to the RF Unit plug 8 pin 2 and finally to Q1 (receiver RF amplifier) on the RF Unit.

29752. TS-820s xformer hookup

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-11 14:52:27 UTC

Topic: 29752 Message: 29752

Howdy to the group,

My first transcever was the TS-820. Years later, a good friend was looking for one so I traded it to him for a HQ-129x. At some point, he has a problem with it and decided to remove the wiring from the transformer to test it. That was about the time he became ill and never made any more progress until he became SK a few years ago.

I got the old 820 from the estate and put it away, thinking that I would tinker with it and try to get it working or part it out. The jumper is missing that plugs in when there is no vfo in place and I think that may have been the problem the whole time.

I aquired the 820, I was unable to get the original manual or the service manual which I sent with it. Cannot find a schematic of the transformer hookup either and although I think I can see how to hook it up, I would like to varify before putting power to the unit.

Where can I find a schematic that shows the power transformer wiring for the TS-820s?

Any help I can receive would be greatly appreciated.

Thanks,

Tom AC5JH

Hi Tom,

You can download the TS-820 operator and service manual at

www.n6wk.com/kenwood/

The rear panel 9 pin socket, without a remote VFO plugged into it, must have pins 8 and 9 shorted with either the factory jumper plug or a short piece of wire.

Tom:

There are a number of places where you can download the manuals and schematics for the TS-820S, including BAMA and Mods.DK.

Also the famous Ken, K4EAA, has a website with really high resolution manuals and schematics. The schematics are at:

http://www.k4eaa.com/schematics.htm

Look around Ken's site and you will find the manuals as well.

Finally, if it would help, I could take a picture of the transformer connections on my TS-820S and e-mail them to you. I think the connections will be pretty obvious if you see them but you should do some continuity checks to make sure.

Good Luck!

Robert

Hello Mike

i made a typo; i meant that RL-1 was NOT the cause of the fault!
In the meanwhile i took out the TIF connector on both sides and cleaned it and put it back
Now the 830 comes more to live!
But i noticed a strang thing i never noticed before: when i switch between usb/lsb, the 830 goes in transmit for a split second.
At the same time i hear that other "hidden relay" switching.
Is this normal?

Topic: 9980 Message: 29756

This may come under the heading of "if it aint broke dont fix it" ??

I have reviewed threads dating back to 2006 where there was flurry of activity related to replacing product detector diodes with Schottky diodes. I am thinking about doing same with my TS-830. I also found some discussion on other forums where authors state this is just a "feel good" mod.

Has anyone who performed the mod performed any actual measurements or side by side comparisons to determine if there really is any performance improvement?

I suppose it cant hurt unless I fool around and lift a foil! Suspect modern receiver design would not use the 1n60 germanium diodes today.

Thanks
Terry K9TW

Hi Ton,

Is the VOX turned ON? If it is, switching modes will cause the 830 to switch, briefly, into TX then back to RX.

Hello, I recently picked up a ts530s, I replaced the hv caps with a kit from ken and then replaced the driver and the finals with a pair of 2001a's. I have set the bias and tuned into a dummy load on 28.1. I believe the only step left is to neutralize the finals. I only have a common digital volt meter here. Is there a way to test across the 50 ohm load with anything other than an o-scope? Thanks, Mike w2waw

Terry,

How are you going to determine whether replacing the diodes actually made a difference or not? Do you have the test equipment to make accurate "before" and "after" measurements? Do you have 2 identical radios, one which will be modified and one which will not? Unless you have the test equipment to perform accurate before and after test I would not recommend changing the diodes.

I agree with your initial statement, "If it ain't broke don't fix it!".

Mike:

You need something that will convert that RF voltage into something a digital VOM can read. That means a diode that will rectify it like a 1N34 or 1N60, in other words, an RF probe. I believe that on his website Ken has the plans for one. If you are using a Heathkit Cantenna dummy load there is one built in. By the way, you do not need to load up power into a dummy load to do that, but you do need a dummy load so that the output is looking into the right impedance.

Robert

Mike,

An RF probe and a VTVM but an o'scope is much more accurate because you can actually see the signal on the screen rather than a meter movement. What ever method you use just be sure you set the SG switch to OFF.

I have a few questions. I mean on disrespect when asking the following questions.

Why did you replace the driver and both final tubes then replace the HV filter capacitors? Did you have a problem that, through troubleshooting, that pointed to these components as the source of the problem or were they simply replaced because they were old? If age was the reason then I'm sorry to say that is a common mistake and a waste of time and money. Components should not be replaced simply because they are old. It is a form of "shot gun" component replacement which is replacing components without any supporting evidence to replace the components and typically results in no overall improvement.

Hello Mike,

yes you were right; VOX was still on and caused a short transmit.
I saw some blue light at the tubes while switching the mode switch, but all solved now!
It seems that replacing the rl-1 relay was not necessary but okay it will last for years now ;)
The TIF cable i think caused the problem.

Thanks for your advice,

Mike --I dont have high quality lab equipment or identical rig to make any meaningful comparisons so that is why I posted the question. It appeared that quite a few people (including experienced old timers) had performed the mod and were claiming improvement. I wanted to know if this was subjective or objective. A good mechanic doesnt need empirical test to tell if multiple carburetors on an engine are balanced. He can tell by listening. I thought maybe this mod was on that order? Also, I see this mod is being performed and discussed on Yaesu forums as well. Tom Rauch W8JI has pretty much said it is bogus and he is pretty well respected. I consider you to be in his class and appreciate your response. I am bored and love to work on rigs, but absent any objective results I think I will take your counsel and leave well enough alone and find someplace else to melt some solder! Tnx Terry

Hi Ton,

Plug 7 on the RF Unit carries the 8Mhz "TIF" (Transmit Intermediate Frequency) signal plus driver tube plate voltage. If it's not making contact then it's quite possible the driver tube will have no plate voltage and the 8Mhz TIF signal will not appear at the input to the transmit mixer (Q6 and Q7).

With the VOX switch set to ON and changing modes noise is produced that is applied to the VOX circuit causing a momentary tripping of the relay. This will happen with all of the hybrid with the VOX switch turned ON and the Mode switch positions changed. This happens with my 820 if I turn VOX OFF.

Have fun and enjoy the 830.

A broken foil run can affect the circuits the relay controls (receiver biasing, driver and both final tube biasing, and switching between receive and transmit).

Hello, No disrespect taken, The previous owner told me the hv caps were on the way out and the finals and driver were not in the rig when I purchased it. If you type in "shotgun" to the search engine here you will see that same advice given a few times. Thanks for the help. Mike w2waw

>
> I have a few questions. I mean on disrespect when asking the following questions.
>
> Why did you replace the driver and both final tubes then replace the HV filter capacitors? Did you have a problem that, through troubleshooting, that pointed to these components as the source of the problem or were they simply replaced because they were old? If age was the reason then I'm sorry to say that is a common mistake and a waste of time and money. Components should not be replaced simply because they are old. It is a form of "shot gun" component replacement which is replacing components without any supporting evidence to replace the components and typically results in no overall improvement.

Topic: 29766 Message: 29766

I read this article below and checked one of my TS830's it seems as if mine on the shaft is 90 deg's out! I bought this radio some time back and it has always worked great. Is the article written in stone as it is said or is there some 830's that align different? I have enjoyed reading all the post on this page and I too do believe if it ain't broke don't fix-it, but at this point I am wondering!

Ken
NZ4Q

To align the bandswitch sections;

Put the radio on 10Mhz. The flats on the shaft should be vertical.
Check the shaft in the final compartment. There should be a flat to
the outside (right side of radio viewed from front) and one to the
bottom. This is the correct alignment.

29767. Crystals for Kenwood TS-820

Ken,

You said the shaft in your 830 is 90 degrees out of alignment. What symptoms, through troubleshooting, are you experiencing that suggest/points to the band switch shaft being out of alignment? Just the article or is the 830 experiencing improper/failure in transmitter tuning of the PI Network (Plate and Load controls) resulting in loss of RF output?

Unless there are problems/symptoms that through troubleshooting suggests/points to the band switch shaft being out of alignment with the final amplifier wafer switches then I recommend not messing with and making changes to the shaft alignment just because you read an article about band switch shaft and wafer switch alignment.

Nothing wrong with my 830 I was cleaning the fan motor area and injecting a couple drops of oil, I read the article looked at mine and its not the same as the article stated. I don't intend on doing anything to my 830 just stating that maybe that article I read here may not right!

kd8hmo,

International Crystal Manufacturing can supply/make just about any crystal you may want/need. They made some new crystals for me to fix a CB HACK in 2 820S's. Service is excellent and prices very fair. Look to spend about $20.00(USD) per...if it is a special order. Take a look at their catalog on-line.....

Topic: 29776 Message: 29776

i have a ts-830 that has 3/4 scale reading on s meter in receive mode with rf gain set for maximum sensitivity. the rig receives signals however they are impacted by this. i have checked the voltages on the af board and all ok. adjusting the 3.6 volts toward a higher voltage impacts the receive signal strength and lowers the s meter reading. any help greatly appreciated.

Topic: 29776 Message: 29778

Do not make any adjustments to the AF Unit voltages that results in higher or lower voltage levels that are not consistent with the voltage levels indicated on page 33, step 1, in the 830 service manual!

If the voltages on the AF Unit are adjusted to the levels shown in step one on page 33 of the 830 service manual and your problem still exist, the problem is not in the AF Unit power supplies.

VR3 on the AF Unit board, with the RF gain control set fully CW and the 830 in receive, sets the receiver's 3.6VDC receive operating bias levels that controls the gain of RF Unit receiver RF amplifier Q1 and IF Unit IF amplifiers Q4 and Q8. It also sets the collector voltages for AGC amplifier Q10 and S meter amplifier Q11. By improperly adjusting VR3 on the AF Unit, causing an increase in voltage above 3.6VDC, you are affecting these amplifiers in a "negative" way and adding more problems than you already have.

The S meter responds to changes in AGC voltage changes based on the strength of the incoming signal. It also responds to the setting of the RF Gain control which varies the operating bias voltage to the amplifiers indicated above.

The voltage at IF Unit plug 15 pin 3 should be approximately 2.9VDC with the RF gain set fully CW and no signal received. Check for -6VDC at IF Unit plug 3 pin 1.

None of these "boat anchors" has a built-in keyer. I have nothing against MFJ but there are lots of keyer kits out there, some very cheap like http://k1el.tripod.com/K12.html. But that one is not as easy a kit as the MFJ kits, you'd have to provide some kind of a case.

You'll need a keyer interface as the voltage on the key cct of the hybrids
is too high for most keyers. There's a good but simple circuit in the files
on the site. Works a treat for me.

Hi Chris,

I'm sorry but that is not true.

The grid block keying voltage at the CW key socket is approximately -61VDC which is well within the maximum CW keying voltage of all CW keyers.

It's funny what you run across when you work on radio equipment. I have been a licensed ham since 1974 and have built or repaired a bunch of radios and related equipment over the years but in all that time and in all those radios I have never found anything like I found last weekend while working on a Kenwood 830-S Transceiver. I just acquired this radio from a friend of mine who was a missionary in Honduras. The VFO was catching about every turn at the top of the travel. I decided to remove the VFO to see if I had some dirt or something in the gears. I removed the knob after I got the unit out and found that it was just pressed on to tight. I readjusted the knob and it took care of the catching problem. When reassembling the radio I looked down and saw something that looked like the top of a broken pilot lamp bulb. I just let it set there and continued to put the rig back together and when I tipped it on it's side something that looked like a big bug fell out. After closer inspection I determined that it was a gecko it was about 3/4" long. What looked like the pilot lamp was it's egg shell.
I guess that goes to show you That not every radio problem is a bug...Some times it's a lizard.
Hope you enjoyed this.

My choice is a simple straight key.
A bencher paddle can be used on one side as a sideways straight key with this radio.
(rather awkward to do)

Hi Norb,

This reminds me another story : I once bought a R-599 Rx on Epay from a German fellow. When it came home, I checked it and thereafter made some cleaning job to discover a dead spider in a corner of the chassis. Beside that, the set worked well.

I gave the seller a good feedback, but reported him what I had found in his set.

He replied that he had counted all of his spiders, that all were at home, and that the extra one could no be his.....

Hi hi hi !!!

None of these "boat anchors" has a built-in keyer. I have nothing against MFJ
but there are lots of keyer kits out there, some very cheap like
http://k1el.tripod.com/K12.html. But that one is not as easy a kit as the MFJ
kits, you'd have to provide some kind of a case.

Hi Chris,

I'm sorry but that is not true.

The grid block keying voltage at the CW key socket is approximately -61VDC which
is well within the maximum CW keying voltage of all CW keyers.

Nick,

When you bought the radio from me, you asked about the "straight key" that was connected. Since I had lost(I knew where it was--blown down) my antenna, I had the straight key connected for demonstration purposes. You inquired about a "keyer." I told you that I used a very simple MFR electronic keyer with my "rock-n-roll" keyer...ie rock one way...roll the other...but due to a shoulder/arm injury that has been difficult to use. Other than using the straight key then and on "straight key night," I have used the electronic keyer and "paddle." Hope the rig is working for you!

Topic: 29796 Message: 29798

Frank,

There are 2 versions (dates) of the 6146W

1. 6146W manufactured before 1964 is a replacement for the 6146A.

2. 6146W manufactured after 1964 is a replacement for the 6146B.

Some will say the 6146A and 6146B has "significant differences" in inter-electrode capacitance and the "A" should not be used in place of the "B". However, when comparing the differences in inter-electrode capacitance, the ONLY difference between the "A" and the "B" is the "Grid #1 to Plate" capacitance

6146A - .22pf
6146B - .24pf

Difference = .02pf

All of the other inter-electrode capacitance values in the 6146A and the 6146B are the same.

A difference of ".02pf", in my opinion, when operating in the tubes in the HF frequency spectrum, is not a "significant difference" in inter-electrode capacitance between the 6146A and the 6146B.

Maximum plate dissipation CSS rating

6146A - 20 watts
6146B - 27 watts

Maximum plate dissipation ICAS rating
6146A - 25 watts
6146B - 35 watts

The different maximum plate dissipation between the "A" and the "B" is due to a heavier plate in the "B".

Legend:
CCS = "Continuous Commercial Service"
ICAS = "Intermittent Commercial Amateur Service"

It is, however, widely accepted "not" to mix 6146A and 6146B tubes. This means you should not use 1 6146A and 1 6146B. The tubes should be in pairs, 2 x 6146A or 2 x 6146B.

You will have to neutralize the final amplifier regardless of the tube version you use.

I am aware of, and have read, Glen Zook's (K9STH) article titled, "The 6146 Family of Tubes", in the files section of this group.

You can review, for your own satisfaction or peace of mind, the specifications for both 6146 versions by entering "6146A specifications" or "6146B specifications" search phrase in your favorite search engine.

It is entirely up to you which version of 6146 you use. I can only provide the specification (inter-electrode capacitance) differences as I see them.

I forgot to answer your question referring to vendors that sell the 6146W.

RF Parts (rfparts.com)
Surplus Sales (surplussales.com)
Vacuum Tubes (vacuumtubes.net)
The Tube Store (thetubestore.com)
The Tube Depot (tubedepot.com)

Radio Daze (radiodaze.com) no longer sells vacuum tubes. They sold their entire vacuum tube inventory to "Vacuum Tubes" (vacuumtubes.com).

There may be others but the list above are a few that I am aware of.

Hi,

Surplus Sales has NOS Circa 1985
GE USA Made finals in B and W
plus the driver tube 12BY7A.

I have used the 6146W in both of my 520 and 530.

Some of the other sellers have tubes imported from China.

Hi Ed,

If you have access to an o'scope, connect the o'scope to the AF Unit plug 1 pin 2 (DET). Tune in a signal off the air, watch the S meter for an increase or fluctuation etc. If there is nothing indicated on the o'scope then there's no detector recovered audio from the IF Unit.

Do this before you turn the 830 on. You want the problem to be occurring when you watch the o'scope.

Ed,

I will try and get a pic up-loaded tomorrow..but in the mean time..the "WARC MOD" has nothing to do with 10m, just 12, 17 & 30meters. You will have to removed the top and bottom covers..be careful of the speaker lead. Turn rig upside down with front facing you. Look on the left side, front for the AF-AVR board #X49-1140-00...really can't miss it. You are looking for CONNECTOR 6..you should be able to see a 6 next to the connector. That area is kind of crowded..so take your time and use some bright light and a magnifier if needed. Find PIN 4 (TOF) it's a small gauge BLUE wire. See if you can pull a bit of slack...then cut. Go to N6WK web site, download a High-resolution manual.....good luck....oh.....you may also have to "tweak" up the antenna, mix, and drive coils..

From: w5rkl
Topic: 29809 Message: 29812

Just because the 830 doesn't transmit on those bands, and as been stated before, 10 meters is not a WARC band, does not mean the WARC bands have not already been enabled. There may be something else that is causing this problem. Therefore, before you cut any wires, you should check the 830 to see if the WARC bands have already been enabled. The possibility your 830 WARC bands have not been enabled are slim. The steps to enable all 3 WARCC bands are in the TS-830 operator's manual, page 27 section 6.5, but, again, do not cut any wires before you check the WARC band enabling steps in the 830 operators manual.

If the WARC bands have already been enabled, further steps will have to be taken to track down the source of your problem.

29813. Re: Heathkit SB-610 or SB-614

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-17 05:08:34 UTC
From: w5rkl
Topic: 29811 Message: 29813

The SB-610 and SB-614 are both RF monitoring scopes that, when connected between the exciter (TS-820) RF output and the antenna, displays the transmit RF envelope of the exciter (TS-820).

While the SB-610 can display limited IF signals from the transceiver, it will not display the type of information the SB-620 does. The SB-610 must have the correct IF transformer installed in order to display the TS-820 8Mhz IF signal.

The SB-614, to the best of my knowledge, does not have the ability to display the IF signal. I could be wrong but I believe it's simply a transmit RF signal monitor and very basic limited bandwidth o'scope.

If you are looking to monitor signals either side of your operating frequency like a Spectrum Analyzer in modern transceivers, the better scope is the SB-620. I wouldn't count on the SB-620 to display signals as well as the modern day Spectrum Analyzers do.

From: w5rkl
Topic: 29814 Message: 29815

Hi Russell,

I have an SM-220 but without the BS5 or BS8 Pan Adaptor module installed. There is room for only "1" band scope adaptor in the SM-220. Selecting and installing the band scope (BS) adaptor depends on the receiver or transceiver used. The band scope adaptors are no longer available from Kenwood. They do appear from time to time on eBay either as an individual module or installed in an SM-220.

The BS-5 Pan Adaptor module, when installed in the SM-220, has an IF frequency of 3.395Mhz which makes it compatible with the Kenwood R-599 receiver, TS-511, TS-520, and TS-900 series transceivers. It also is compatible with numerous Heathkit transceivers and receivers such as the SB-300, SB-301 and SB-303 line of ham band receives and the HW-100, HW-101, SB-100, SB-101, and SB-102 line of ham band transceivers all of which have a 3.395Mhz IF frequency.

The BS-8 has an IF frequency of 8.830Mhz which makes it compatible with the TS-530, TS-820, TS-830, TS-120, TS-130, and a number of other line of Kenwood transceivers with 8.8Mhz IF frequencies.

Regardless of the band scope module installed in the SM-220, modifications to the receiver or transceiver will be required to connect the band scope to the receiver or transceiver.

No modifications to the transceiver or transmitter are required if you simply monitor the transmitter or transceiver's RF output.

You can download the SM-220 operators manual at Gordon's website

n6wk.com/kenwood/

The last communication that I had with Bob was that he was going to be out of the area until the 14th so depending on how backed up he is he should get back up with you pretty quick and I am certain he has all the knobs you could want because the last time I checked he had about 50 hybrid radios on his shelves just waiting to be parted out.

He also ships very quickly, even if he has been pummeled by a snow storm!

29817. Re: warc bands

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-17 16:10:52 UTC
From: w5rkl
Topic: 29809 Message: 29817

One additional comment. If you use the high resolution TS-830 schematic, D4 is not shown on the schematic. The 830's operators manual says to cut both end of the "TOF" line between the IF and AF unit or clip diodes D4, D5, and D6. If you search for D4 on the high resolution schematic you won't find it. D4 is, however, shown on the 830 RF Unit schematic in the 830 service manual which is directly above D5 on the RF unit schematic.

There was no mention whether receive on the bands in question is working. Therefore, if loss of receive on the bands in question has also occurred, then it's possible wafer switch S1-1 on the RF Unit as a possible suspect.

The RF Unit band switch wafer S1-1 controls the selecting of the individual band's PLL Unit VCO oscillator by applying a voltage (9VDC) to the individual band's VCO oscillator selection diodes. Loss of individual band's VCO oscillator diode select voltage, through switch wafer S1-1, will result in loss of VCO oscillator signal to the RF Unit. When this happens both transmit and receive fail on the bands in question.

I recommend checking RF Unit plugs 1 and 2 and plug 4 on the Counter Unit to ensure they are clean and mounted flush with the RF and Counter Unit boards. I also recommend checking S7 to ensure it's in the correct position and plug 5 on the Counter Unit to ensure it is clean and mounted flush with the Counter Unit board. In addition, check plug 3 on the Counter Unit is clean and flush with the Counter Unit board and plug 1 on the PLL Unit is also clean and flush with the PLL Unit board. Also clean the bandswitch wafers, including switch wafer S1-1, using contact cleaner. Use only enough to do the job. Rotate the bandswitch fully CCW and CW a number of times. The use canned air to remove any/all contact cleaner residue. Wait a few minutes (see warnings on the contact cleaner can) then test for proper operation.

Switch "S7" I mentioned is the front panel ".5" push button switch. Make sure it is in the correct "pressed" or "not pressed" position for the selected 10 meter band. See the 830 operators manual for details on how to use this switch.

Hi All

I'm new to the list and have a question. I'm about to do the same thing to my 530S and have this question. I have read the up grade in the manual and it sounds like cutting this one blue wire will enable all of the WARC bands is this what happens? I also read that by cutting two diodes, D5&D6, out that it will also enable the WARC bands, but only 12 & 17 meters. After this is done the drive will have to be set on the two enabled bands.

Subject: [TS-520_820_530_830] Re: warc bands

Just because the 830 doesn't transmit on those bands, and as been stated before, 10 meters is not a WARC band, does not mean the WARC bands have not already been enabled. There may be something else that is causing this problem. Therefore, before you cut any wires, you should check the 830 to see if the WARC bands have already been enabled. The possibility your 830 WARC bands have not been enabled are slim. The steps to enable all 3 WARCC bands are in the TS-830 operator's manual, page 27 section 6.5, but, again, do not cut any wires before you check the WARC band enabling steps in the 830 operators manual.

If the WARC bands have already been enabled, further steps will have to be taken to track down the source of your problem.

Howdy Guys,

Thanks for the info on the 820s. After some tinkering, looks like the transformer may be the culprate.

If I thought it was a cheap/easy fix, I would be interested in working on it. I would love the have the old rig in my shack. But, looks like it ain't and I already have too many projects.

I live near Okla City and have a daughter living in Dallas. Anyone in my area that might be interested in a TS-820s, in need of some work or for parts, can contact me and maybe we can figger out some kind of swap. I would be happy to meet you somewhere along the way or in my immediate area and turn it over to you.

Email me at ac5jh@...

I would have thought most, if not all, hybrids, TS-530 and TS-830, have their WARC bands already enabled by now. However, I would at least check, using Gordon's picture and the operator's manual as a guide, to determine if the WARC bands have already been enabled. If they have already been enabled then there's no need to cut any wires.

It sure is nice outside today, partly sunny and 75. All the snow is long gone. Suppose to stay like this until at least next week. It could stay like this all summer long!! Reminds me of Germany during the spring and early summer, nice with medium temperatures. Great for sitting on the back patio enjoying the squirrels and birds eating at the bird feeders. We have one old brown squirrel, he's big and fat, who has been around for the past 3 or 4 years and he loves to hang from one of the feeders and chow down. When it snows the big black birds come by the dozens to feed. So many the smaller Cardinals and other birds don't have a chance. The dogs chase the black birds away so the smaller birds can have a nibble or two.

Tom,

Have you measured the resistance of both primary windings? It should be low resistance across each individual primary winding, somewhere around 8 ohms or so. If you have completely disconnected the transformer from the Rectifier Unit and dial lamps and and heater etc then when power is applied to the primaries the fuse blows, then you are probably right, the transformer is bad. It could be any one of the windings that's shorted, whether between the windings themselves or between separate windings. An ohm meter connected between separate windings will give you an idea where the short may be.

What are you looking for a trade?

Awesome! Thanks so much, Gordon. I too wondered about the diodes. Cutting one wire is certainly simpler.

Gordon and group

I cut the blue this afternoon and the radio loaded right up on all of the WARC bands. Also thanks for the email about how to do it and yes I did read the manual , but it always makes me feel better when I hear that someone else had did it and there weren't any surprises .

Thanks again

Carl

Awesome! Thanks so much, Gordon. I too wondered about the diodes. Cutting one wire is certainly simpler.

Carl,
I uploaded a file that shows exactly which wire to cut on the TS-830/530 to enable the WARC bands it if in the files section here.

Howdy Guys,

Thanks for the info on the 820s. After some tinkering, looks like the transformer may be the culprate.

If I thought it was a cheap/easy fix, I would be interested in working on it. I would love the have the old rig in my shack. But, looks like it ain't and I already have too many projects.

I live near Okla City and have a daughter living in Dallas. Anyone in my area that might be interested in a TS-820s, in need of some work or for parts, can contact me and maybe we can figger out some kind of swap. I would be happy to meet you somewhere along the way or in my immediate area and turn it over to you.

Email me at ac5jh@...

Hello all and particularly you Mike W5RKL. I have a Kenwood TS-820 radio. Given the choice of either or would you recommend a Kenwood SM-220 with the BS-8 Pan Adapter or a Heathkit SB-620 set for 455KHz IF ?

Thanks
73,
Russell

From: w5rkl
Topic: 29827 Message: 29828

Good morning Russell,

If it were me I would go with the SM-220 with the BS-8 band scope installed.

The IF frequency in the 820 is *8Mhz". A Heathkit monitor scope with a 455Khz IF can will not work with the 820 as a Band Scope.

29829. AGC Problem?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-18 11:29:28 UTC
From: k3bmk
Topic: 29829 Message: 29829

I have a baffling agc problem which I need some assistance in figuring out.

When my AGC switch is flipped to "off" I get a high pitched tone. When the mode switch is USB the pitch of the tone is a bit lower than when the switch is in LSB.

When the AGC switch is flipped to fast or slow the tone goes away.

Not really sure where to start at troubleshooting this issue.

Any assistance would be appreciated!

Thanks!

Brian

Brian,

When the tone appears, with the AGC switch turned OFF, tuning the VFO to a higher or lower frequency, does the tone vary in frequency and/or disappear?

The AGC switch has nothing to do with receive frequency control or anything other than the receiver's gain control.

29833. Re: tune up ts-830s

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-18 17:49:19 UTC
From: w5rkl
Topic: 29830 Message: 29833

Hi Ed,

First, the CAR control is only used in TUNE and CW modes, never in SSB mode. The CAR control is disabled in USB and LSB modes.

The CAR control, when used in TUNE mode during tuning of the transmitter, controls the level of RF signal applied to the driver tube. Normally an initial CAR control setting between 9 and 11 o'clock will produce an initial increase in ALC meter indication. When that happens, adjust the DRIVE control for a peak ALC meter indication. If the meter pegs fully CW, rotate the CAR control CCW so the meter points to about 12 o'clock then continue adjusting the DRIVE control for a peak indication on the meter (meter switch set to ALC). Once you have peaked the ALC meter, switch the meter switch to IP. Rotate the PLATE control for the lowest (dip) IP meter indication. At this point, if your 830 is connected to a watt meter, the watt meter should display an increase in RF output. While watching the watt meter, adjust the LOAD control for a peak RF indication on the watt meter. The IP meter will most likely not be indicating 225ma but an IP current indication somewhat less. Unkey the transmitter. Set the MODE switch to CW. If you have a plug inserted into the rear CW socket, remove it. Key the transmitter with the SEND switch and with the meter in IP, adjust the PLATE control slightly for any further reduction in meter indication. If the meter exceeds 225ma, rotate the CAR control so the meter is 225ma. At this point the watt meter should display 100 watts output. If it does, you are done, don't touch anything, unkey the transmitter.

The MIC gain should be set, in USB or LSB modes, so normal voice levels at a distance of a couple of inches from the microphone, with the meter set to ALC, should result in the ALC meter just kicking up above zero. The ALC meter should not be constantly at the maximum ALC scale. If it is, rotate the MIC gain so the ALC meter just kicks up above zero. That is the best setting for lowest distortion and best sounding transmit signal. This is assuming you are not using an amplified microphone such as an amplified D-104 or some other amplified microphone with the microphone gain set too high.

ED
read the tune up procedure for the rig in the manual.Mic and Carrier settings will depend on what mic you use and proper meter readings on tuneup. If you don't have a copy of the manual,unplug the rig till you get one.'
thanks

The carrier control for CW; advance to The point you get power and after tuning up,reduce the setting until you get a slight drop of power output.

This control has No effect on SSB.
Mic. setting; advance while speaking into a mic and with Meter set for ALC reading When you reach the point where meter moves up slightly into the ALC area on the meter on voice peaks and stop there. This will have different positions for different microfones.
This control has no effect in CW mode

Tom:

Look up Jim, AF4AT, here on QRZ and ask him if he still has the transformer for the TS-820 he was parting out.

Just thinnk, This may have been the only WARC band radio that hadn't been freed
to work the WARC bands....

29847. Automated RX antenna switch

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-19 15:21:13 UTC
From: pakjan830
Topic: 29847 Message: 29847

Hi all,

I would like to be able to use a separate RX antenna (small loop) with my TS-830S which I need to switch over automatically to the TX antenna whenever PTT is activated.

How I was hoping to do that is by utilizing the RX-TX relay contacts at the rear accessory connector to switch a coaxial relay which connects the other antenna to the antenna input. I am a little bit concerned about hot switching the signal and thereby damaging relay or radio.

Are there any specs as to the timing between when the relay switches and when power is present at the antenna plug or does this happen in the same instant?

How does an external PA handle this? Does it reduce output power via ALC until it has completed its switching cycle?

73 de Jan, DK3LJ

RADIOHF - Kenwood TS830S Gold With ESP Mods

Kenwood TS-830 Gold with ESP (Electronic Service Professionals ESP Mods)
cost of mods $485.00
Expanded Receive audio Mod > Expanded transmit audio Mod > Tunable peak IF filter Mod >Unlocked IF shift /VBT Mod
The radio performs perfectly it will receive and transmit at 3.1k wide has new set of 6146 tubes and new driver tube 100 Watts on all bands just a great radio no marks or dents from non smoker (no smell of smoke) I use a MXL R144 Ribbon Microphone with the radio not included with the radio,(But is also for sale)I have the manual . $750.00 +cost of shipping no Paypal USPS Money order of personal check Ok you will have to wait till the check clears before I ship

I ***NEVER** trust anyone who will not take PayPal. Right..send a M.O. for $700.00 plus dollars....Someone think I am nuts? Here ....take my money and run.

I have used PayPal since their start and have never had a problem. Those who have issues with PayPal, have ~usually~ created them themselves. Sure, they charge me a fee, but to me, it is worth it to get my money when I sell something. Needless to say, anything I have sold, has been advertised honestly and guaranteed.

First, unless there is power output when the relay switches, there will be no damage.

Second, with zero power output to an external amplifier then there will be "zero" ALC produced and fed from the amplifier. ALC is not a "constant" gain control voltage from a power supply. The TS-830's ALC is produce ONLY when grid current flows in the final tubes and that requires an RF signal being applied at a level that causes the final tube grids to swing "positive" during a portion of the positive half of the RF cycle. Some, not all, external amplifiers produce ALC by rectifying the RF driving signal then feeding that rectified voltage back across the ALC connection to the TS-830 to reduce the gain. If the TS-830 is not providing any RF output then there will be no ALC produced or fed back from the amplifier to the TS-830.

29854. SM-220 replacement CRT?

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-19 20:34:05 UTC
From: Charles
Topic: 29854 Message: 29854

I was repairing my SM-220 and the CRT fell to a carpeted floor. Apparently, the impact was enough to kill the tube. (I will not drop the CRT, I will not drop the CRT, I will not drop...)Hey, it happens.
Anyway, does anyone know of a source for a replacement? I've Googled my clumsy digits to the bone but have come up empty.
I imagine that I'll just end up buying another one on ebay, but I thought that I'd give this group a shot first.
Anybody?

Good Afternoon Charlie:

Just a thought... I do remember seeing new old stock CRT's for the SM-220 on eBay... as recently as the last quarter of 2010. It maybe worthwhile to place an ad on the usual... QRZ, EHAM and QTH. You never know, you may just get lucky.

Good hunting...

tnx es 73

If someone could give me a part number for this CRT, I can poke around at Fair Radio Sales.

Here are some stock numbers that might be useful that I found for this CRT.

National Item Identification Number

01-211-8344
012118344
5960-01-211-8344
5960012118344

National Stock Number

Item Name

ELECTRON TUBE

Federal Supply Class

5960

Description

An inclosure, including two or more electrodes, in which a flow of electrons may occur through a vacuum or a contained gas. The electronic conduction takes place either by means of electrons emitted from a cathode or by ionization of the contained gas. Includes phototubes (photoemissive type only), Geiger-Mueller tubes, traveling wave tubes, cathode ray tubes and microwave tubes (Klystron, magnetron, or the like). Excludes items whose primary purpose is to produce light energy. Also excludes PHOTOELECTRIC CELL; and SEMICONDUCTOR DEVICE (as modified).

Darn! I figured that this would turn out to be another "unicorn hunt." Discontinued parts are rather annoying at times, aren't they?
Oh, well, it's part of the hobby.
I see that someone already supplied the part number (Toshiba 75ARB31), so it looks like I'll just start sniffing around on eBay or QTH.
Thanks, guys.

I just got a rig with WARC bands and what not. Don't want to see my faithful 520S sitting around gathering dust. I am a minimalist and don't believe in keeping stuff I don't use around. It is in excellent condition, and I am currently using it, till the new rig arrives. I operate mostly digital with it, so I will throw in the signalink interface cable with it. Along with a Shure 450 microphone, and Yaesu mike that I use on SSB with it. I will send you the manuals as well. $300 plus $50 shipping. I will be at the Sussex, DE Ham Fest in April with it, if it doesn't sell by then. You can power it up, and test it all you like there. Thanks. Chris KG4AZN

29864. Kenwood Screen Saver

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-20 17:39:04 UTC
From: sceneryguru
Topic: 29864 Message: 29864

Good Morning Group:

I for one, spend more time then I would care to admit, in front of a computer monitor. And thought that it might be nice to have something enjoyable to look at to break the monotony during the day.

I wanted to float a proposition to the group, regarding the idea of a professionally produced screen saver dedicated to our prized Kenwood hybrids, encompassing all the various models.

I would be happy to coordinate the collection effort required in obtaining the (high resolution) photographs. Once satisfied that the best images are in hand, I will proceed to fabricate the screen saver software. The photos will include the equipment model numbers, station call and QTH.

The finished software will be compatible across the spectrum of Windows OS 98/Me/NT/2000/2003/XP/Vista/Win7.

In closing, the proposed screen saver would be available exclusively, to all group members at no cost, via a download from the groups Yahoo Website.

I look forward to any and all constructive feedback regarding this initiative. Here's your opportunity to immortalize the ol' station, as well as to share it with your peers.

tnx es 73

Tom G, Sr.

That only works in the same state the 'fraud' was committed in. If the guy lived in, say, California, and you lived in, say, New York, the cost of going to California to sue him (or to hire an attorney to represent you in court) would be cost prohibitive.

I agree, I have heard stories about bad transactions involving Pay Pal, but I have never experienced more than one. In that case, a fellow sent me a stereo set and used hard plastic videocassette cases to "cushion" the unit. It was fairly banged up when it arrived, but worked quite well. I am just sorry that it had a dinged corner on it, because I had always wanted that Marantz stereo !

But that was his ignorance, and not a Pay Pal issue. So I really don't know what all the grief is all about.

Hi amigos !
Have a Kenwood FM rig TK260 25 Watts 2 meters band
I need to program it using the front panel buttons, not
the computer interface.
Anyone here has an idea how this can be done...
BTW... my TS820 is working fine on receive after the
Noise Limiter switch is kept in the turned OFF position !!!

29878. Update on lost 9VDC

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-21 01:43:23 UTC
From: ae5uu
Topic: 29878 Message: 29878

I should have mentioned in my earlier post concerning no 9VDC at the pin 8-pin 9 jumper of the VFO jack, that I do have the 900v main supply present. At first I had 60ma idle current and then, when I tried to maximum the Drive control with the meter on ALC, the needle pinned and the 6A fuse blew. I replaced the fuse, once again I have 900V, but now I don't have 60ma idle current. Thanks for any ideas.

I agree, I have heard stories about bad transactions involving Pay Pal, but I have never experienced more than one. In that case, a fellow sent me a stereo set and used hard plastic videocassette cases to "cushion" the unit. It was fairly banged up when it arrived, but worked quite well. I am just sorry that it had a dinged corner on it, because I had always wanted that Marantz stereo !

But that was his ignorance, and not a Pay Pal issue. So I really don't know what all the grief is all about.

OK, so I had to look it up, but here's my experience: I have made 933 purchases over the last 2 or 3 years and two of them have gone bad (purchase not delivered). In both cases the loss was covered by PayPal and I have not lost a dime. I wish all of life was that satisfactory. YMMV, but if anyone wants to sell me something they will need to accept PayPal.

Hello Mike...My radio is a TS-820. One further bit of information; whatever my problem is it was caused by some contacting mistake that I made while replacing that useless 9 pin VFO jack with an 8 pin microphone jack. To venture a guess, I must have inadvertently shorted pin 8 or pin 9 to ground briefly by mistake. I have read the past posts on this subject, but have not as yet come up with the solution. Thanks for your help.

Good Morning Group:

Thanks for the positive feedback regarding the Kenwood Vintage Screen Saver project.

To clarify a couple of issues that were raised by the group;

Yes... the photographs on the groups website can be used if, they are high resolution images, no smaller than 1024 W x 768 H. Which begs the question... which images? shall I comb through them and select the best or would the members like to pick the candidate and forward to me as an attachment vis e-mail?.

I would like to ID each graphic: Equipment featured, Call and QTH.

In closing; Gordon your offer of the scanned spec'sheets is perfect. We can interspace the station photos with spec' sheets. Please send them and all other graphics to me as attachments to my e-mail. Please keep the Kenwood Screen Saver as the subject line.

tnx es 73

DG-5's become available on ebay all the time. They sell anywhere from below $100 to $170+. At least four have sold in the last three weeks. I got the one I use (flawless) for $80 plus shipping. Go to ebay, do a search for Kenwood DG-5 then save the search. You will get instant notification when one is listed. It looks much better than the after market one and down the road if you decide to sell the 520S it will be alot easier to sell with the "correct" frequency display. Collectors are very serious about having correct parts or attachments for their their collections, whether their passion be radios, cars, airplanes, cycles or what ever. Get the Kenwood.
Regards,
Butch Lewis

If you cant find a DG-5, check this guy out. He is building custom "DG-5" displays.

From: w5rkl
Topic: 29888 Message: 29890

If you have zero voltage at plug AF1 pins 1 or 2 check for 14VDC at the AF Unit's plug AF1 pin 3, it should be approximately 14VDC. Lost of 14VDC at AF1 pin 3 can be traced to the 14VDC supply filter circuit on the Relay Unit (X43-1110-00).

The 9VDC from the AF Unit provides LV for all the solid state circuits. Since you have no 9VDC I suspect the VFO, RIT, FIX-R, and RIT LEDs no longer illuminate. Receive and transmit also have failed. You may hear some low level noise with the volume control turned up all the way but that's no indication the receiver's working! You also loss the 3.3VDC receiver bias voltage on AF2 pin 6 as well.

If the 14VDC supply is working, you measure 14VDC at AF1 pin 3, then it's possible Q4, Q5, Q6, and/or Q7 have failed on the AF Unit. Q4 thru Q7 are the 9VDC supply transistor that reduce the 14VDC down to 9VDC and regulate the 9VDC output. Pot VR4 on the AF Unit board adjusts the level of 9VDC at AF1 pins 1 and 2. It also regulates the 3.3VDC receiver bias voltage. The 3.3VDC bias voltage is obtained through pot VR1 on the AF Unit board. VR1 simply reduces the 9VDC down to 3.3VDC through VR1 by adjusting VR1 for 3.3VDC on AF3 pin 6.

Remove your AF AVR Unit board. Look on the foil side for a number. The number will either be "J25-1381-03" or "J25-1381-13". This is the AF AVR Unit board "design" number. Not all AF AVR Unit boards for the 820 are the same!! A replacement board must have the same "J25" foil side number as the one in your 820 otherwise it will NOT work in your 820! I know because I just replaced the AF AVR Unit board in my 820 and found this out! The AF AVR Unit board in the 820 service manual that shows the component and foil image is is NOT the same as the 820 service manual's AF AVR Unit schematic! The foil/component view is a "J25-1381-03" board while the AF AVR Unit schematic is for the "J25-1381-13" board!

You can either replace the defective component(s), Q4, Q5, Q6, or Q7 and possibly D5 (6.1 volt zener) on the AF AVR Unit board or you can purchase a replacement AF AVR Unit board from Bob Mansker, ke5ftf at mail.com.

From: w5rkl
Topic: 29891 Message: 29892

Russell,

Okay, first connect your volt meter to AF1 pin 1 or 2. Next, adjust VR4 on the AF AVR Unit for 9VDC +/- .5VDC. Next, connect your volt meter to AF2 pin 6 and adjust VR1 for 3.3VDC. Recheck AF1 pin 1 or 2, voltage should still be 9VDC. If so then you are done with the LV adjustment.

Make sure you adjust VR4 for the "9 volts" FIRST followed by VR1 for the 3.3VDC. Do NOT adjust VR1 first then VR4 as that will make the 3.3VDC receiver operating bias voltage level "too high"!!

Check for the presence of 9VDC at the following plug and pins in receive:

IF Unit IF1 pin 5
CAR Unit CJ2 "USB" (mode switch set to TUNE, CW, and USB)
CAR Unit CJ2 "LSB" (Mode switch set to LSB and FSK)
PLL Unit terminal labeled "9"
FIX VOX Unit "FX3" pin 1
Relay Unit RL2 pins 10 and 14, RL1 pins 1, 2, and 3
RF Unit RF2 pin 1

Set the FUNCTION switch to "FIX-R" and note the FIX LED lites. Set the FUNCTION switch to VFO, FIX LED should extinguish.

Push RIT button, RIT LED should lite. Reset (release) RIT button, RIT LED should extinguish.

Push RF ATT push button, ATT LED should lite. Reset (release) RF ATT button, ATT LED should extinguish.

Next, remove the 2 prong plug on the rear of the VFO. Connect one ohm meter lead to the "LARGE" pin and the other meter lead to one of the wires on the rear 8 pin socket you replaced the external VFO socket with. One will show continuity, zero ohms. That wire also connects to pin "8" on the normal 9 pin remote VFO socket on the rear panel.

If you have a 9 volt battery you can connect the "+" battery terminal to the wire that connects to the "LARGE" VFO plug pin and the "-" battery terminal to ground. Plug the 2 prong plug back into the VFO. The 820, when powered up, should receive and if the 820 has the digital display, the digital display should light up showing the frequency. If you try this battery test, make absolutely sure you have the correct wire to the "LARGE" pin on the VFO plug!!!

Topic: 29893 Message: 29893

Mike,

You have suggested that I should have:

VF-1 pin 1 9vdc to ground I have 11.82vdc
VF-1 pin 2 9vdc to ground I have 11.82vdc
VF-1 pin 3 14vdc to ground I have 14.98vdc
VF-2 pin 6 3.3vdc to ground I have 4.65vdc

It seems that all of my voltages are a little hot. I have checked the calibration on my meter; it is accurate.

Moving right along, the orange and the red wire from that miserable VFO panel jack (that is responsible for all this) are soldered together. However I also tap off the expected 9vdc from this point for the Electronic Specialty Products DD-103 Universal Digital Dial that I have always used with success in this fashion (Signal and shield are also taken from the VFO panel jack, pin 1 signal, pin 2 shield.) There is NO voltage at this point at the junction of the red and the orange wires.

I still have 900 volts from the high voltage supply. I do not show the 60 ma current that I am looking for. None of the rest of the normal tune up controls are functional today.

No LEDs light up. The only lights that do light up are the panel meter lights.

After that I am dead in the water. I keep reading the posts on this issue, but have not made sense of it yet. What do you think of my voltage readings and the fact there is no 9vdc at the VFO panel jack orange and red wires?

29894. coax rf connector needed for TS-930 (and possibly others)

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-21 21:16:56 UTC
From: Chris Parnell
Topic: 29894 Message: 29894

Kenwood part number E04-0157-05 is the RF coax in and out sockets (mini jack) on the PA final unit of the TS-930s / 940s and probably other older radios too (hence me posting it to the hybrid group too).
.
They are angled mini coax receptacles that solder to the PCB to accept coax input from the Signal unit (930s) to the PA unit and the coax out from the PA unit to the ANT tuner unit (930s).

I need to obtain 4☐. Does anyone have any?

Thanks
Chris, ZL1CDP

Russell,

You either misread or missed the segment of my response where I said to "adjust" VR4 on the AF AVR Unit for 9VDC at AF1 pin 1 or 2 and adjust "VR1" on the AF AVR Unit for 3.3VDC on AF2 pin 6!

Okay on the LEDs not lighting up. We can work on those later.

Russell,

After you adjust the 9VDC (VR4 on the AF AVR UNIT) and the 3.3VDC (VR1 on the AF AVR UNIT), measure the final tube grid voltage.

Make sure the rear panel SG switch is set to ON.

Measure the Rectifier Unit's "-C" bias voltage at RF Unit plug RF2 pin 7. It should be approximately "-110VDC" or so.

Next, measure the bias voltage at the Final Unit PC board's "FG" terminal. The voltage should be approximately "-100VDC" in receive and in transmit, "-55VDC". In transmit, this voltage, with no RF applied from the driver tube, should "vary" when the rear panel's BIAS POT is rotated CW or CCW.

Measure the Final Unit's screen voltage at the "SG" terminal on the Final Unit PC board. The voltage should be approximately "+255VDC" in receive and approximately "+210VDC" in transmit.

If the "FG" and "SG" Final Unit PC board terminal voltages do NOT change, remain the same whether in receive or transmit, the final tubes are NOT conducting!

Mike,

1) First off, I now have 9vdc and 3.3vdc in the radio. I still have no 9vdc at the VFO panel jack pins 8 & 9.
2) At the IF unit, pin 5 I had nothing but my schematic indicated that I would find 14vdc on pin 4, which I did (15.24vdc.)
3) At the PLL Unit terminal 9 I had nothing, no matter what mode the radio was switched on.
4) At the FIX VOX Unit FX3 pin 1 I had 13.21vdc.
5) In the Relay Unit RL2 I found 15.22vdc on pin 10, and nothing on pin 14. However I did find 5vdc on pin 13. RL1, pins 1, 2, and 3 I had nothing.
6) In the RF Unit RF2 pin 1 I found nothing.
7) No LED lights anywhere.
8) The VFO resistance measurement were a little confusing. When the radio was turned off, the resistance was 2.52KOhms. When the radio was turned on, the resistance read high ohms.
9) No joy using a 12vdc battery.
10) The Rectifier Unit's "-c"bias voltage at the RF plug RF2, pin 7 was 118vdc.
11) In the Final Unit PC board, I could not find a terminal "FG". I did find IPM, SG, PD1, PU2, DRV, H, MR1, and MR2. There was no voltage at any of these terminals. The relay clicks when I key the microphone, but I still did not find any voltage on the Final Unit's terminals, including "SG".

I very much appreciate your continued advice.

73,
Russell

You say there is 15.22VDC on Relay Unit RL2 pin 10. If you pull the relay from the Relay Unit, that voltage on pin 10 should be "zero".

The wrong voltages such as RL2 pin 10 and lack of voltage on RF2 pin 1 tells me a couple of things:

1. The female sockets inside the plugs are not making contact with the board pins

2. Some of the pins on the boards may have bad solder/broken connections to the foil runs on the foil side

3. Broken wires in the wiring harness

4. Your meter lead is not making contact with the female socket inside the plugs

etc...

Having 15.22VDC on Relay Unit plug RL2 pin 10 is simply wrong. The same applies to FIX VOX Unit plug FX3 pin 1 which should be 9VDC "directly", through the wiring harness, from the AF AVR Unit plug AF1 pins 1 and 2!

With the relay in the socket on the Relay Unit and the relay NOT energized, relay plug RL2 pin 14 has 9VDC "directly" from the AF AVR Unit plug AF1 pin 1 and 2 through the wiring harness that is applied through relay terminals RL-12 to relay plug RL2 pin 10! Therefore, the voltage on RL2 pin 10 should have "9VDC" not "15.22VDC"!

Are you using the schematic to trace and measure the voltages? If not then you should. I recommend wrapping a small solid wire around the tip of your volt meter probe when measuring voltages at the plug pins. Strip back about 1/2 inch of bare solid wire and wrap one end around the volt meter's probe then wrap electric tape around the probe's tip. This will keep the wire attached to the probe. Strip back about 1/4" of outer covering exposing the bare solid wire. Attach the black negative lead to the chassis and insert the red positive probe with wire attached into the plug's pin. A pin that should have a voltage that did not in previous measurements may now show voltage. Do not do this when measuring 210VDC or higher without using care to prevent receiving a shock!

Never troubleshoot when you are tired or frustrated. Mistakes are easily made that can harm or even kill you. Always use standard safety precautions when taking voltage measurements.

One additional comment for Russell.

I never said to use a "12 volt" battery! Where did you get the idea to use a "12 volt" battery?

I agree, never attempt to measure resistance in a "live" circuit!

Mike,

I will run through all the tests again tomorrow, taking into account your last 2 postings. I will post the results when I have them.

Sounds like a power supply de-coupling problem to me. Have you checked all the electrolytics that are used to bypass the power supply from the RF floating around the inside of the set?

If the gain is advanced all the way, there is a high possibility that a signal is leaking to where it shouldn't be getting, and causing a positive feedback (oscillation) situation.

Electrolytics do dry out and lose the ability to filter out those high frequencies, and you might never catch the problem by simply measuring D.C. voltages. Use a scope, and check any place where audio or RF signals should be bypassed to ground. There should be no significant AC signals there! If you find a signal of the proper frequency, that comes and goes when you change the gain , you have found the bad part, but caps are not that expensive, and sometimes re-capping a radio is an excellent restoration step.

29904. HV board mystery

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-22 05:20:35 UTC
From: kevin
Topic: 29904 Message: 29904

I am checking the resistors on my 520 HV board. When I got to R7 I noticed that the schematic only goes to R6. I have an extra parts 520X which has an HV board with 6 resistors, the same as the schematic. Both boards have the same part number on them. Any ideas?

Topic: 29904 Message: 29905

Hey Kevin, without looking at mine I can't be sure but I can tell you that some of the boards are interchangeable with little to no modification between the 520 radios. Someone may have swapped out the board from another rig perhaps? I had a discussion with Mike W5RKL about this when troubleshooting my AF Unit. Kenwood apparently made little design changes here and there during the manufacturing process but they should have changed the part number of the board if they made a design change to the schematic. The fact that your boards are the same part number is kind of odd.

I ran into this sort of thing with my 2 520s where one has a dial light and the other does not. I know the earlier versions of the 520's VFO's did not come with lit dials but in my case, the later serial number is the one without the lights so I figure the VFO was replaced at some point. Unless you're the original owner, I would suspect that the board was taken from another model radio as the schematic that I have also shows up to R6.

Hi Mike, thanks for the answer!

That would be the scenario for a SSB QSO if I understand you right (as no power is ouput when not speaking). What would happen though if I had the same in a VOX activated PSK or CW QSO? Does the VOX cater for a delay between PTT and the emission of HF?

Hello Jan,

What you are talking about is a relay sequencing switching circuit that controls the activation and switching of the antenna relay "first" then activating the transmitter second when switching from receive to transmit. When switching back to receive, the opposite sequence occurs, the transmitter activation relay releases "first" following by the antenna change over relay "last". You can't achieve this by connecting a separate antenna change relay controlled by the TS-830's amplifier relay terminals on the Remote socket.

While such a circuit can be easily controlled with PTT, CW break-in would require a bit more key switching and break-in control.

Simply connecting an external antenna change relay to the TS-830's Remote socket amplifier relay terminals will not accomplish this. When the TS-830 is keyed and the relays are energized, there is a millisecond of delay when the 830's internal relay energizes fully then activating the external relay, switching the antennas in transmit. The sequence operates in the same manner when switching back to receive, the 830's internal relay releases "first" then the antenna change over relay releases "second".

29908. AF AVR Unit VR4 to adjust pin 1 & 2 to 9vdc

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-22 14:11:20 UTC
From: ae5uu
Topic: 29908 Message: 29908

Good morning Mike,

I have started over, with the test lead modification that you recommended (works well.)

AF AVR Unit AF1 pins 1 & 2 11.82vdc
AF AVR Unit AF1 pin 3 14.58vdc
AF AVR Unit AF2 pin 6 3.58vdc

No matter what I adjust VR4 to, the voltage remains at 11.82vdc.

I thought I had better submit this before I go any further since I know that I have a problem here.

73,

Russell

Morning Russell,

Yes, I agree, your AF AVR Unit board appears to have a problem. It's appears one or more of the 4 transistors in the 9 volt supply are bad. Which one would require some testing at the component level. Before fixing any further problems you would have to fix the AF AVR Unit board. Having 11.82 volts on the 9VDC supply can and will affect the VFO and other 9 volt circuits. Hopefully the extra 2 volts has not damaged the other 9 volt circuits.

A quick fix is to replace the AF AVR Unit board in your 820. Bob Mansker, ke5ftf at mail.com may have a used AF AVR Unit board. You should remove the AF AVR Unit board, turn it over, and find the "J25" number. The number will either be "J25-1381-03" or "J35-1381-13". The replacement board must have the same "J25" number as the AF AVR Unit board your 820 now has. I have both AF AVR Unit boards here, a "J25-1381-03" and a "J25-1381-03". My e-mail address is good here and on qrz.com.

hi,
Does a facility exist to lower the sidetone of the transmitted CW note on the TS830S ? I dont know if doing so would impact on a narrow CW filter that I have installed on the rig. I know 800hz or thereabouts appears to be the norm but I prefer a lower note, say 600hz thru 750hz. Is there a pot onboard which will provide for this or is it fixed ?

Hi Will,

Unfortunately there isn't a pot that changed the frequency of the CW sidetone, only the sidetone volume level (VR1 on the AF Unit). Also, the CW sidetone does not flow through the crystal filters. The CW sidetone is applied to only "2" places

1. The receiver's audio amplifier so the operator can hear his/her dits and dahs

and

2. The VOX circuit for CW break-in

The CW sidetone is not applied to any other circuit.

The CW sidetone oscillator is Q1 and supporting component on the 830's AF Unit. Fixed C2, C3, C4, C5 and fixed resistors R5, R6, and R7 affect the audio frequency of the CW sidetone.

Hi Mike,

Sorry Mike but I disagree.

I have a P1 Touch Paddle Keyer (www.cwtouchkeyer.com). The supplied documentation states "This keyer output circuit is designed to switch key input of 13.8 volts or less. Do not attempt to use this output with a vacuum tube transmitter (either grid blocked or cathode keyed).

I also use a Link-All-3.0 interface which would lock on after about ten minutes use. I modified it with the single transistor grid block keying cct in the files section and for the past two years or so it's performed without a hiccup. Having said this I must say I also use a Watson "W-CRIK" key with no interface and that's fine.

73
Chris SV0XBQ/9

There are probably a lot of keyers that have no problem with 61vdc but not all. (unless I've been unlucky to find the only two that don't)

Hi Chris,

I'll admit, and correct my "all keyer" statement, that your keyer appears to be one of the few exceptions. However, when referring to the Kenwood hybrid keying voltage as being excessively high, -60VDC is not considered to be an excessive keying voltage. This is the typical CW grid blocking keying voltage for many, not all, vintage transmitters and transceivers. There are, however, some vintage transmitters that use cathode keying where the CW keying voltage is much higher, on the order of 100VDC and higher.

The only time I have experienced failure in a keyer is when I plugged an Heathkit HD-10 keyer into a Swan 350. The HD-10 maximum keying voltage is -105VDC at 20ma, if I remember correctly, and the moment I plugged the HD-10 into the 350 the HD-10 keying transistor failed, was shorted internally.

Anyway, thanks for the information on your keyer.

Mike, I had an old Multi-Elmac AF-67 that used Cathode Keying. You are right, the voltage was in excess of 100 volts, key up. You had to remember to put the button contact of a straight key on the cathode side of the circuit, and not the frame, or you could get a nasty shock! Don't ask me how I know this !

29919. Lost 9vdc saga continues

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-22 17:37:07 UTC

Mike,

I getting over my frustration at not being on the air daily. I am starting to enjoy this search process, the majority enabled by your guidance.

As I said, I have removed the AF AVR board. It is a "J25-1381-13".
I removed VR4 and found it to read 600 ohms across the coil, which is not too far off the specified 500 ohms (R12-0042-05) I should think. The center tap works correctly from each end.

So you suggest that we are talking about 1 or more of the 4 transisters in the 9vdc circuit, Q4, Q5, and Q6 (all 2SC372, part number V03-0099-05) and or Q7 (2SA496, part number V11-0113-05)). Can I test this, with the transistors either on or off the circuit board using my only tool, a volt-ohm meter?

You also mention D5 Zener diode (WZ-061, the number in my book, but not necessarily the one in my radio as my book is a Pdf file, part number V11-0243-05 also from my book). These are all easy to access. Are the individual parts expensive? Do you think that I could find them at Radio Shack?

I no doubt will purchase your board (through PayPal), and appreciate the opportunity to do so. In the meantime I am keeping myself busy. Am I wasting my time with this?

73,

Russell

Hi Russell,

I doubt you will find the components at Radio Shack. I replaced D5 with a 6 volt zener. D5 is a WZ-061, 6.1 volt zener. I found Q7 (2SA496(Y)) at a component warehouse but I can't remember the web address or company name. I bought 10 of them, they were priced at $1 each, so I have new 2SA496(Y) transistors that I can send you one along with the 6 volt zener diode for D5, also new. I have not cross referenced Q4, Q5, and Q6 with a replacement NPN transistor simply because Q4 thru Q6 were not bad. I replaced Q7 because my 820 was drifting more than factory specs. After replacing Q7 with a new 2SA496, the drift settled down to within the manual's factory specs.

Jim,

I have a Heathkit Apache TX-1 and the CW keying voltage is, if I remember correctly, about 130VDC or so. I remember keying it with an Eico 747 tube keyer which has a reed relay to key the circuit. I wouldn't think of using my MFJ-407 or HD-10 keyer. YOu could sure tell it was a vintage transmitter by the initial make when the CW key was closed, a very slight chirp could be heard even with the differential keying circuit the Apache used.

Heathkit used -60VDC or so grid block keying in their SB and HW line of 5 band transceivers (HW-100/101 and SB-100/101/102) and their hybrid HX-1681 transmitter. I believe the Heathkit DX20, DX-40, and DX-60 used cathode keying as well. I had a Hallicrafters HT-32 that used grid block CW keying which worked very well with my HD-10 keyer.

In the case of the Heathkit HX-1681, there is solid state circuitry within the power supply circuit board that provides for a low voltage at the key jack.

My HX-1681 has an open-circuit voltage of +5.9 V and a short-circuit current of 1.25 mA at the key jack.

Alan, KD5R

I can't imagine what my first Novice rig, a Multi-Elmac AF-67 sounded like over the air! Good thing that most hams looked the other way when they heard a Novice call on the air, with a chirpy, clicky, drifting signal ! I never got an "O O" report, so maybe it wasn't so bad, after all!

Too bad those days didn't last longer. My second rig was a Central Electronics 100V, and that was PURE PLEASURE to operate! Coupled with a 75A-4, was like being in HEAVEN !

Ahhh, Memories !

Subject: [TS-520_820_530_830] Re: Sending CW with the TS-530s

Jim,

I have a Heathkit Apache TX-1 and the CW keying voltage is, if I remember correctly, about 130VDC or so. I remember keying it with an Eico 747 tube keyer which has a reed relay to key the circuit. I wouldn't think of using my MFJ-407 or HD-10 keyer. YOu could sure tell it was a vintage transmitter by the initial make when the CW key was closed, a very slight chirp could be heard even with the differential keying circuit the Apache used.

Heathkit used -60VDC or so grid block keying in their SB and HW line of 5 band transceivers (HW-100/101 and SB-100/101/102) and their hybrid HX-1681 transmitter. I believe the Heathkit DX20, DX-40, and DX-60 used cathode keying as well. I had a Hallicrafters HT-32 that used grid block CW keying which worked very well with my HD-10 keyer.

> Hi Chris,
>
> I'll admit, and correct my "all keyer" statement, that your keyer appears to be one of the few exceptions. However, when referring to the Kenwood hybrid keying voltage as being excessively high, -60VDC is not considered to be an excessive keying voltage. This is the typical CW grid blocking keying voltage for many, not all, vintage transmitters and transceivers. There are, however, some vintage transmitters that use cathode keying where the CW keying voltage is much higher, on the order of 100VDC and higher.
>
> The only time I have experienced failure in a keyer is when I plugged an Heathkit HD-10 keyer into a Swan 350. The HD-10 maximum keying voltage is -105VDC at 20ma, if I remember correctly, and the moment I plugged the HD-10 into the 350 the HD-10 keying transistor failed, was shorted internally.

I modified it with the single transistor grid block keying cct in the files section and for the past two years or so it's performed without a hiccup. Having said this I must say I also use a Watson "W-CRIK" key with no interface and that's fine.

Hi Everybody,

First of all, thanks for approving my membership application so quickly. I see this can be a very busy group so I'll probably switch to the digest mode. The mail I have read so far is very encouraging. People are helpful and courteous even when mistakes are made.

I have a set of the 599 twins. Some time in the 80s I took a ham friend to a somewhat distant swap n swindle... er.. hamfest. All the way there he talked about how much he wanted a set of twins. Drake twins. Heath twins. Collins twins. Any twins. So about an hour into the flea market I saw this nice looking set of Kenwood twins with a matching speaker. I called my buddy and he bought them for $250. The seller assured him of course "they work fine business". Much later I saw my friend at work and asked about his new toys. He set his coffee cup down and moaned. "They don't work". And it's worse - a member of our local club had a set with new finals that actually did work for $200! He bought those. Next day I went to his house and looked inside the transmitter... parts missing! I offered him $200 for the broken rig (the receiver seemed to be OK). He jumped all over that and I took the transmitter and receiver to my car. I came back for the speaker but it was still connected to his other new rig. I asked for that. He complained that I was only paying $200! I pointed out the rig doesn't work. I got the speaker, too <evil grin>. I repaired the transmitter and had the twins on the air two days later. I still have them and still use them. Over the years I've made two or three other repairs as the equipment ages. But I find the twins pretty easy to work on..even for me.

73,

Bill KU8H

HI Bill,

Sounds like you got a good deal!! Did the R599 comes with the 6 and 2 meter converters? If it did they would be mounted on the top right rear inside the receiver. I have an R599A receiver with both 6 and 2 meter converters installed. The 6 meter converter works but the 2 meter converter oscillates, something I have not yet worked on. One of many projects I have waiting to be tackled.

The R599 receive is a nice receiver. I wish it had an IF Shift control but unfortunately it doesn't. The CW filter is very good. I use it with a Drake T4XB transmitter, I had to add a mute circuit so the R599 muting circuit would be compatible with the Drake xmtr mute circuit. It's a simple one transistor switch. Easy to use and works very well.

Anyway, welcome to the group. If you have any questions about your twins or any other Kenwood hybrids, even technical questions not related to a transceiver etc, feel free to ask.

Hi Jon,

You might try cleaning and tightening all PC board mounting screws. The foil side of the boards, when mounted in the 830, act as grounds. Over time the mounting screws become lose and corrosion sets in, affecting the board grounds.

Check chassis ground screws as well, they too can become lose which affects the ground.

Until you clean and tighten all mounting screws I would change any filter caps just yet.

Topic: 29933 Message: 29933

Hello Group

Well, troubleshooting and refurishing a TS-830S. All working well, with one problem. the 17 meter band has very low output.

To answer the obvious responses:

1. The TOF line has been cut, so opened up for WARC bands.
2. ALC does peak well on receive, It reacts nicely to aligning with both ANT and RF coils.
3. On transmit, I get NO ALC in either TUNE or CW mode. With FULL CAR on CW mode, I can peak up the output with the DRIVE, TUNE, LOAD controls, as well as adjusting the 18mhz coil. About 7 watts output.
4. I inspected the underside of the RF board, there is no problem there.
5. I removed the 17m coil (L29), no burning, good continuity.
6. I tried several 12BY7A drivers, all act the same.

SO .....

All I can see that remains untested is the C37, the 18pf capacitor that is across the coil for the 17m DRIVE alignment.

Anything else that I am missing?

Thanks and 73

Kevin K7ZS

The PC boards in the hybrids have ground foil on the foil side around the mounting holes. If the ground foil around the holes that mate with the chassis mounting hardware gets corroded, the foil side grounds will be affected. What I typically do is to remove the mounting screws and wet a piece of stiff card board with contact cleaner, slide the card board between the bottom of the board and the mounting screw hardware on the chassis, press the board gently against the card board and slide the card board out from between the bottom of the board and the mounting hardware. I do this until the cardboard comes out clean, not discolored. I change the card board for each pass between the board and the chassis mounting hardware. This ensures a clean foil ground between the PC board and the chassis mounting hardware. I replace the mounting screw and move on to the next hole.

If the LV, 2200ufd 25VDC filter capacitor have high internal leakage current, AC ripple can appear on the 14VDC supply. The 14VDC supply is the source voltage for the "9VDC" and "3.3VDC" supply in the hybrids. The supplies are located in the 520 on the FIX CH AVR Unit board, the "AF AVR Unit" board in the 820, and the "AF Unit" board in the 530 and 830. The filter capacitors, 2200ufd, are located on the bottom right rear in the 520 series (2 axial lead capacitors), on the Relay Unit in the 820 series (2 radial lead capacitors), and the AF Unit board in the 530 and 830 (2 radial lead capacitors).

If you have access to a scope, you can connect the scope to the output of the 14VDC supply to see if there is any AC ripple on the 14VDC supply. If there is AC ripple on the output of the 14VDC supply there is a good chance there will be AC ripple on the 9VDC and 3VDC supplies as well. For connections to the output of the 14VDC supply, check the appropriate transceiver's schematic. The "input" to the 14VDC supply, the connection where the "14VAC" is applied, is labeled "14". There you will see AC ripple. It's the "output" of the 14VDC supply you need to look at with the scope.

Hi Kevin,

The driver tube has nothing to do with your problem nor are the final tubes. Changing the driver tube should be done when the initial tune up step, peaking the ALC with the DRIVE control in TUNE mode with the transmitter keyed, results in a peak ALC indication but the ALC indication begins to drop back towards zero. That indicates a weak/failing driver tube. There should be more than enough drive from the driver tube to peg the ALC meter in TUNE mode during tune up with the CAR control set between 9 and 11 o'clock when adjusting the DRIVE control. In CW mode, unless you turn the CAR control up to between 2 and 3 o'clock, you will not see an ALC indication in transmit. ALC is not used in CW mode as a gain control, the CAR control is used.

What you see on the meter in receive is not "ALC". The meter, in receive, displays the variations in the output of the "AGC" amplifier to the meter amplifiers, based on the incoming signal strength as it is being processed in the "IF" stage on the IF Unit board. Although ALC and AGC both do the same thing, they are different. ALC is a "transmitter" gain control voltage and is only used in "transmit" (USB and LSB modes), never in receive. ALC has nothing to do with nor will ALC be present in the receiver. As I said, ALC is a transmitter gain control voltage and ALC is produced only when grid current flows in the final tubes and only in transmit, never in receive. Since the final tubes are biased to cut off in receive there is no chance of ALC being produced and displayed in receiver. Besides, the relay on the AF Unit "disables" all meter switch positions in receive, allowing only receive signal levels to be displayed as S Units.

I recommend checking the PLL Unit individual band frequencies. This is covered in the TS-830 service manual, step 9 page 35. You will need a frequency counter for this check.

Hello !!! hope all is doing well ... just got finished rebuilding the final stage on my 820 and last night my good ole trusty TS-830s stopped transmitting . Before I open her was hoping to build up a cheat sheet of helpful " go here first hints" .. I keyed up the rig to dip my plate and tune, noticed very odd reaction on the meter. tried to load and guess what !!! only 10 watts output. Flipped over to LSB and keyed mike with meter on HV scale and nothing < very little>.
I tried the simple things .. put a know good driver tube and finale tubes still same reaction . this was a sudden drop off.. did not give any symptoms before it happened. clue... I did screw up and key rig without antenna or dummy load , maybe popped a diode or something? Going to break out the manual and read up ... hope to get some feedback here!! thanks for reading !

PS-
RECEIVER works perfect

Hi Mike

Thanks for the detailed reply, and I guess was referring to the meter action when in the ALC position. By clarifying what it means depending on mode of operation, and further transmit mode, I learned a lot!

I guess the point I was trying to make, is that the receive is working 100 percent, and the transmit functions 100 percent on all bands, with plenty of ALC from the driver tube, no power fading etc..

Also, in receive it is 'right on' frequency wise, and the receiver is extremely sensitive. That is why I dismissed the PLL as a source of this single band really low output. I have a good antenna, and I was able to work a Costa Rica station from here in Oregon, with only ~5 watts output, so it all works, just extremely low output on 17m only.

I do have a good counter, and have done the VCO adjustments many times before. I usually use both the voltage and frequency method. The VFO does tune all the way from end to end, I have seen them before where the oscillator will quit when the VCO is too far off proper calibration.

Stay tuned, I will report what I find after performing the VCO alignment.

Thanks Mike

Vy 73 -Kevin

Thanks Mike,

Mine has the two meter converter but not the six meter converter. The converter works. The R599 does FM too and I tried it on some of the local two meter repeaters. It's probably more useful to me on ten meter FM and I'll use the channelized VHF FM radio on those repeaters. I have thought about making a six meter converter for it. Mine has a 250 Hz CW filter in it. That works really well!

Apparently you don't have the matching transmitter. RIT doesn't mean very much when we use a separate transmitter (which the twins can accommodate).

Hi Mike

OK, VCO check on the PLL board indicated everything was very close to the spec voltage, and all of the frequencies being generated were also right on.

After re-reading your message, now I have a question, regarding the meaning of the ALC indication seen during the transmit DRIVE alignment.

The setup is for the mode switch to be in CW, the CAR control at 12 o'clock, the Screen Grid switch off, and the meter switch set to ALC. 1st step, of course, is setting the bandswitch and moving the VFO to the proper frequency (to find the center of the band) and then peaking ALC in RECEIVE with a fairly strong received signal (like so many, I use the CALIBRATOR).

Switching the standby switch to SEND, you again peak the meter by adjusting the band coil on the DRV board for PEAK ALC. Hmmmmm..... what is causing the meter to deflect?

Since the SG switch is off, the tubes are not conducting, so why does the ALC circuit (indicating grid current is flowing, or is that wrong?)

I note that the PLATE and LOAD settings are irrelevant in this process, so I am curious why the ALC is deflecting when there is no current flowing in the tube, since the SG switch setting makes it impossible.

REASON FOR ASKING: I have noticed that the PLATE CURRENT DIPS FINE when in CW mode on 17m, but the peak output is with the LOAD CONTROL all the way to the left, with output rising all the way to the stop. Leads me to think the PI network on the output is not right, indicating a bandswitch issue IN THE TANK CIRCUIT.

I appreciate you sharing your wisdom with all of us Mike!

Note that the selectivity control can be used in the 25 KHz position for ultra wide band AM reception or even in the CW position if you like to copy a dozen stations all at the same time. My R-599D came without the 6 and 2 meter converters but when I heard the Twins were being discontinued, I search around several dealers and found both of them. The converters are not stellar performers as is, and also require an input impedance fairly close to 50 ohms, or they will have the tendency to go into oscillation.

Good morning Kevin,

I see folks continue referring to receive meter indications as "ALC". ALC is never displayed on the meter in "receive". What is displayed on the meter in receive is variations in "AGC" gain control voltage, not variations in "ALC". Respectfully, it's important to understand and use the correct gain control terminology when referring to gain control voltages in receive and transmit. ALC is a transmitter gain control voltage and only occurs in "transmit", never in receive. AGC is a "receiver" gain control voltage and only occurs in "receive", never in "transmit".

Why does the meter switch not display ALC, IP, RF, HV, and COMP signal/voltage levels while in receive? It's because the meter switch is "disabled" in receive and "enabled" in transmit by the relay on the AF Unit through plug 7. Read on for an explanation how this occurs.

In receive, the AF Unit plug 7 Pin "6" is label "M" for "Meter" and the relay on the AF Unit is shown "not energized" (830 is in receive). If you follow AF Unit plug 7 pin 6 up through the relay terminals you will notice it ends at AF Unit plug 10 pin 6 which is labeled "SM" for "S Meter". AF Unit plug 10 Pin 6 continues through the wiring harness to the IF Unit plug 9 pin 2 which is labeled "SM", again for "S Meter". IF Unit plug 9 Pin 2 continues through the IF Unit board to the "collector" of "Q12". The "voltage" applied to Q12's "Base", in receive, is the receiver's "AGC" voltage from the AGC circuit and any variation in "AGC" receiver gain control voltage will appear on Q12's "collector" fed along the path through IF Unit to IF Unit plug 9 pin 2 (SM) to AF Unit plug 10 pin 6 (SM) down through AF Unit relay terminals to plug 7 pin 6 (M) and out to the meter, displaying "S Units". The level of "S Meter" reading is determined by the level of IF signal applied to the AGC circuit on the IF Unit that is then applied to the Base of Q12. Throughout this receive meter circuit, there is no path to the meter switch. Therefore, the meter cannot and will not ever display "ALC, IP, HV, RF, and COMP" signal/voltage/current levels while the 830 is in receive.

When the 830 is in transmit, however, the meter's signal/voltage path changes when the AF Unit relay is energized. When the AF Unit relay is energized the meter at AF Unit plug 7 pin 6 so the meter path now flows from plug 7 pin 6 through the relay terminals to AF Unit plug 7 pin 2 "TM" (Transmit Meter). The path continues from AF Unit plug 7 pin 2 (TM) through the wiring hardness to the meter switch wiper S13. Depending on the meter switch position determines what signal/voltage/current level is displayed on the meter in "transmit".

The above discussions is how the meter is "disabled" in receive and "enabled" in transmit.

Again, I mean no disrespect when discussing the differences between ALC and AGC. It is important to understand the differences between AGC and ALC and to use the correct terminology when referring between the 2 so as not to confuse or mislead discussions.

Okay, why does the ALC meter show an indication when the "SG" switch is set to OFF since the final tubes are not conducting in transmit? Are the final tubes completely shut off

with no conduction taking place with the SG switch set to OFF? No, not really. The SG switch prevents conduction from occurring between the cathode and plate but NOT between the cathode and "grid"!

The SG switch, when placed in the "OFF" position, applies a "Negative" potential to the final tube screens. As electrons are emitted from the cathode and they attempt to flow to the plate, they are met with a "negative" potential on the screen which forces them "back onto the cathode" so the electrons never reach the plate, therefore, no conduction between the cathode and plate occurs. However, the negative potential on the screen has no control over electron flow between the cathode and grid! Therefore, when the driver tube's RF sine wave signal, when applied to the final tube grids, is at a positive sine wave level that results in the final tube grids to swing "positive", a current "WILL" flow between the final tube cathodes and grids even when the SG switch is set to the "OFF" position. As I said, the negative potential applied to the final tube grids with the SG switch in the OFF position has no control what so ever over electron flow between the cathode and grid when the grids are positive. That's why you can see ALC indication, in transmit, when the SG switch is set to "OFF".

I hope that answers your question. Again, I mean on disrespect in my discussion pertaining to the difference between ALC and AGC. I only mean to ensure folks understand the difference between the two gain control voltages, how and when they are produced and used, and the importance of using the correct terminology.

I agree with you Pete. I use the 25Khz position when operating "AM". The 2.5Khz selectivity position, in AM, is too narrow for acceptable AM reception.

My R599A had been messed with, "Golden Screw Driver" attack..:) The VFO would not tune above 275 on the dial, reached the mechanical stop before the top of the dial. Although the calibrator signal appeared to be close at 25Khz intervals, I use the term "appeared" loosely, the VFO coil and padding variable capacitor were both adjusted wrong. I also found the CW carrier oscillator variable capacitor does not rotate properly to adjust the CW carrier oscillator crystal slightly. That's okay because the CW oscillator crystal is very close to it's crystal frequency so I'll leave it as is, not change/replace the capacitor.

I like the R599A and yes, you are right, I do not have the T599 transmitter. I don't use the RIT, have it set to 12 o'clock with or without the RF gain control pushed in or pulled out.

I like the smoothness of the dial. When I purchased the R599A the dial was rough and the analog dial scarped the rear of the front panel. I had to move the dial back away from the rear of the front panel to fix that. Now it tunes smooth and quite.

Some day I'll find a T599A to match the R599A but for now, I use it with the Drake transmitter.

Hi Mike

No problem on your excellent and emphatic discussion of ALC vs AGC! Through that you educucated us, and explained a lot of the inner workings of the TS-830, which obviously you know VERY well! Of course when you are trying to help folks remotely, proper terminology can be the difference between success and confusion. Thanks for your patience with us!

And, FASCINATING as to why we see an ALC indication with SG off. I now understand - GRID current flows sine the screen is negative, making the grid the only game in town, and since that is the measure used to determine the amount of ALC in effect, we can use it gauge the drive level. Excellent, and now it's part of the archives here, which is super for all of us!

As to my single band problem, I spent all evening going through every S1 switch contact, and all of the contacts in the RF compartment switch. De-Ox-It carefully with a Q-tip (again!) Also, of course, I performed the VCO adjustment per the manual, both with voltage and taking the frequency at D40 on the PLL board. That all looks OK.

NEW QUESTION: How would one, without a sophisticated audio generator, adjust ALC MAX control VR7 on the IF board? The step (#31, ALC ADJUSTMENT in the service manual) calls for a 5mv 1.5khz audio signal to be fed into the mic connector with the ability to bring it to 10mv. Any tricks?

Lastly, any clues besides the obvious bandswitch S1-7 that could cause low drive level on 17m? I've run out of ideas short of removing the S1-7 wafer and carefully ohming out the contacts.

THANKS MIKE for sharing your incredible knowledge here on the Hybrid Junkie forum!

Hi Kevin,

ALC alignemnt step 31 is in 3 parts.

The first part sets the meter to zero with the meter switch set to ALC and the transmitter keyed in sideband with mic gain set to minimum with no audio signal applied to the microphone socket. This is important for not only the second section but also for the ALC meter scale to be as accurate as possible. This is "similar" to the S meter zero adjustments for the receiver with no incoming signal.

The second part sets the ALC meter sensitivity with a set level of audio applied in sideband to the 830. With 1.5Khz at 5mv fed to the microphone socket and MIC gain set fully CW, adjusting VR6 on the IF Unit board will result in the ALC meter just resting at zero. If VR6 is adjusted incorrectly then the meter will not rest at zero resulting in a false ALC meter reading.

The last part sets the ALC meter output at a signal level of 10mv fed to the microphone. If this adjustment, VR7 on the IF Unit, is not adjusted properly then the ALC meter scale will not be as accurate as it can possible be.

I do not recommend using any other method to make alignment step 31. Follow the steps, using the signal levels and equipment mentions so the alignment is done properly. Don't side step or try an alternate method as you could easily end up with an improperly adjusted ALC sensitivity and gain settings resulting in improper/false ALC readings. The 1.5Khz tone is used so the RF carrier signal, modulated with the 1.5Khz tone signal, flowing through the IF stage will be at maximum. This makes adjusting the ALC more accurate then simply adjusting for zero by "guessing". Remember, I have always said, never guess, always check. I'll add "use the right procedures (follow the alignment instructions in the service manual) to ensure the adjustment is done right. Your 830 will thank you and so will the folks you talk to on the air.

Greetings group!

I picked up an 830S at a garage sale. It is a full filtered GOLD edition. Have spent the last few days cleaning it up..kinda looked like a sawdust bomb went off inside. It puts out full power, except on 160 meter band, 70 watts tops. I was looking around on the RF board and noticed L4 (right by the 1.8Mhz ANT coil) slug appears damaged. Would this account for the low output? All other bands appear fine. I tried "tweaking" the ANT, MIX, and DRIVE coils, with no luck?

Does anyone know of a way to use a Heathkit frequency meter to display the frequency of the TS-520SE? I picked up the meter a few weeks ago for general use, but was thinking it'd be nice to use with my Kenwood as well.

Thanks in advance!

No easy way to use a "regular" frequency counter, without some addtional circuitry, to view actual frequency of the TS-520SE. You're better off finding a Kenwood DG-5 or Spectronics DD-1K digital displays that were designed to work with rigs like the TS-520 series.

29949. AF AVR board in TS-820

Yahoo group: TS-520_820_530_830 (2011-01 — 2011-06)
Date: 2011-02-25 13:32:22 UTC
From: ae5uu
Topic: 29949 Message: 29949

Good morning Mike,

On further analysis of my troublesome AF AVR board last night, I discovered that all six pins on AF1 and five out of six pins on AF2 had failed solder joints where they connect to the board. Very strange. I repaired this and hoped for a better output from my board but no joy. My 9vdc output is still 11.2 vdc and the position of VR4 still makes no difference. I look forward to receiving the used board from you today and thanks again. I miss being on the air.

Well, that is true to an extent. You would NOT be able to use a counter to measure the receive frequency of a 520 or any other superhetrodyne design, without some sort of offset calibration capabilities, but you COULD measure the transmit frequency in an indirect way. Even that would give you some error, since there is no carrier in SSB mode, and I believe it is offset enough to produce a tone from the other station when in the CW mode.

So I would agree, there really is no way to actually view the actual frequency without making those compensations!

Hi Russell,

That happens with those old boards from time to time. Let me know when the board arrives. The board 9VDC and 3.3VDC adjustments should be right but I would recommend checking them to be sure. Check and, if necessary, adjust the 9VDC VR4 first followed by the 3.3VDC VR1 last.

Hopefully when you get the board and installed it things will start working. Naturally you will have to make sure the 9VDC to the VFO be present at the VFO plug. You can pull the VFO 2 pin plug from the back of the VFO and measure the voltage from the larger of the 2 pins for 9VDC. The voltage for the VFO goes through the FUNCTION switch to the rear VFO socket then through the jumper plug or short piece of wire between pins 8 and 9 to the larger of the 2 VFO pins on the VFO plug. I seem to remember you replaced that 9 pin socket, if I'm wrong let me know, with another plug of some sort. Just be sure none of the wires are shorted except wires to the original 9 pin socket, pins 8 and 9.

Good morning Robert,

Your problem appears to be a dirty VFO variable capacitor shaft to frame connection inside the VFO.

With the 520 right side up, front panel facing you, remove the top cover. Be careful not to break the top cover speaker wire when removing the top cover. The speaker cable unplugs from the speaker.

The VFO metal enclosure is directly behind the front panel. On the right side is a small metal plate held to the VFO enclosure with 2 phillips head screws. Remove one screw and loosen the other. Move the plate so you can see inside the VFO. The VFO variable capacitor can be seen through the square hole. At the rear of the VFO variable capacitor is a metal fork that is attached at one end to the capacitor's frame and the other end slides over the capacitor's shaft. The area where the fork slides onto the shaft can become corroded/dirty. Give this area a shot of contact cleaner then rotate the VFO fully CW and CCW a few times. Then, using canned air you can buy at Walmart, blow the excess contact cleaner and any dirt with canned air. Use just enough contact cleaner to do the job. You may have to do this a couple of times depending on how dirty the connection is.

It's also possible the front bearings on the VFO variable capacitor are also contributing to this problem, the grease may have dried out. If cleaning the fork connection fixes the problem then you can stop and secure the side plate onto the VFO enclosure.

Read and adhere to all warnings/cautions on the contact cleaner can. Contact cleaner is flammable and it only takes a small spark to ignite it. Use just enough to do the job, don't soak the area with cleaner. Always use generous amounts of canned air to remove any/all cleaner residue then wait 3 to 5 minutes before applying power. Always follow all safety precautions and remove ALL power plugs from the wall outlet and wait for all power supplies to bleed to zero before putting your hands inside the radio.

Well, I didn't think there was an easy way, but one can hope. What about the hard way? Do you think if I pulled up the schematics on the DG-5 I could figure out a way to build interface circuitry?

It's not a big deal if I can't get it to work, I mainly got the meter to use for testing and repairs. I also got a RF signal generator, function generator, and a nice little lab power supply for $10 each when I got the frequency meter.

Maybe someday though I'll figure out something, or find a DG-5 for a good price when I have the money.

Good morning Joe,

L4 is one of the receiver's "8.83Mhz" trap coils. I recommend checking and, if necessary, make adjustments as needed in step 18 on page 37 in the 830 service manual.

Good morning James,

I agree with the other response, the best route, whether easy or difficult, is to obtain a DG-5 digital display or the other aftermarket digital display.

The digital display requires circuitry that accepts the "VFO", "HET" and "CAR" oscillator signals that are mixed/counted by digital circuity along with an internal digital circuit reference oscillator in the digital display circuit itself in order to produce the accurate frequency that is then applied to a digital display circuit. The accuracy of any digital display is not only based on the accuracy of the 3 rear panel RCA sockets that have the required oscillator signals (VFO, HET, and CAR) but also the accuracy of digital displays internal reference oscillator.

Mike & group,

I did those steps prior to posting the msg, but rechecked them again. The 160m band appears the only one with lower output. However, I got out a better magnifier and some really bright light and took a further look at L4 on the RF board. The slug is damaged, half of it appears missing, there was some type of glue applied to the top, and I can see the fine copper wires and they "don't look right." So, I guess I'll root around the parts bin. Is there another coil that can be taken from another board? I have other boards, but not sure that I have an RF board. Oh, on further inspection, it also appears that some of the wiring on the counter board and the PLL have/had been altered. From what I can figure out it may have had or an attempted CB hack. Just my luck.
